

MESOBLAST PHASE 3 TRIAL SHOWS THAT A SINGLE INJECTION OF REXLEMESTROCEL-L + HYALURONIC ACID CARRIER RESULTS IN AT LEAST TWO YEARS OF PAIN REDUCTION WITH OPIOID SPARING ACTIVITY IN PATIENTS WITH CHRONIC LOW BACK PAIN DUE TO DEGENERATIVE DISC DISEASE

Melbourne, Australia; February 11, and New York, USA; February 10, 2021: Mesoblast Limited (ASX:MSB; Nasdaq:MESO), global leader in allogeneic cellular medicines for inflammatory diseases, today announced results from the Phase 3 randomized controlled trial of its allogeneic mesenchymal precursor cell (MPC) therapy rexllestrocel-L in 404 enrolled patients with chronic low back pain (CLBP) due to degenerative disc disease (DDD) refractory to conventional treatments. The results indicate that a single injection of rexllestrocel-L may provide a safe, durable, and effective opioid-sparing therapy for patients with chronic inflammatory back pain due to degenerative disc disease, and that greatest benefits are seen when administered earlier in the disease process before irreversible fibrosis of the intervertebral disc has occurred.

"The durable pain reduction for at least two years from a single administration indicates that rexllestrocel-L has the potential to change the treatment paradigm for chronic low back pain due to inflammatory disc disease, a condition that affects as many as seven million patients across the United States and Europe, and to prevent or reduce opioid use and dependence" said Dr Silviu Itescu, Chief Executive Officer of Mesoblast.

Patients were randomized 1:1:1 to receive a single intra-discal injection of either rexllestrocel-L using a unit dose of 6 million allogeneic mesenchymal precursor cells (MPCs), with or without hyaluronic acid (HA) carrier, or saline control, and stratified for opioid use at baseline to ensure all three treatment arms were equally represented in this pre-defined population. The study was conducted across 48 sites, predominantly in the United States. In a previous randomized controlled trial in patients with refractory CLBP, up to 80% of whom were taking opioids, a single injection of 6 million MPC + HA carrier significantly reduced CLBP for at least two years, while HA alone was no different than saline.¹

The effectiveness of rexllestrocel-L alone or rexllestrocel-L + HA through 24 months was evaluated on reduction in pain using Visual Analog Score (VAS) and on disability or function using two measurements, Oswestry Disability Index (ODI) and EuroQoL 5-Dimensional (EQ-5D) Index. Key analyses were performed on the total study population and on the pre-specified subsets of opioid users at baseline and patients with CLBP duration shorter or longer than the median for the whole study population.

Regulatory approval of pharmaceutical agents, such as opioids, in the treatment of chronic pain syndromes generally requires reduction in pain as the primary outcome. In the midst of the opioid epidemic in the United States, the Food and Drug Administration has prioritized a focus on new therapeutics that target both pain reduction and opioid avoidance², particularly for treating CLBP which accounts for 50% of opioid prescriptions.³⁻⁵ In addition to assessing the durability of pain reduction with rexllestrocel-L treatment, this study evaluated primary outcomes using composite measures of pain reduction together with functional responses to treatment, as well as exploratory composites of pain reduction and functional responses in the context of opioid reduction.

A single injection of MPC + Hyaluronic Acid (HA) carrier resulted in:

- Achievement of significant and durable reductions in CLBP through 24 months across the entire evaluable study population (n=391) compared with saline controls
- Greatest pain reduction observed in the pre-specified population with CLBP of shorter duration than the study median of 68 months (n=194), significantly greater reduction at all time points (1, 3, 6, 12, 18 and 24 months) compared with saline controls

- Significantly greater pain reduction in the pre-specified patient subset of opioid users (n=168) at all time-points compared with saline controls
- Confirmation of durable pain reduction seen with the combination of rexlemestrocel-L + HA in the previous randomized controlled trial, where HA control alone was not significantly different from saline¹
- Increased composite outcomes of reduction in pain together with improvement in function in those with CLBP of shorter duration than 68 months, the median for the study; however, the composite outcomes of pain and function did not reach statistical significance across the entire study
- No safety concerns over the 24-month period of follow-up in the entire study population

Importantly, in patients using opioids at baseline, the results showed:

- Significant reduction in opioid use over 24 months in patients treated with MPC + HA, while increased opioid use occurred in saline controls
- Treatment with MPC + HA resulted in nearly four times more opioid users achieving 50% reduction in pain as well as reduction in opioid use by 24 months than those treated with saline

Mesoblast will meet with the FDA to discuss the results from this trial together with the earlier randomized controlled trial of MPC + HA, and potential approval pathways for rexlemestrocel-L + HA as treatment for durable reduction in CLBP due to DDD with opioid sparing activity.

Entire Treated Population of Patients

Across the entire treated population in the Phase 3 trial (n=391 evaluable at follow-up), patients who received a single injection of MPC + HA had a significantly greater reduction in pain at both 12 and 24 months compared with saline controls as measured by VAS on a scale of 1-100. *Figure 1* shows the least-squared (LS) mean change from baseline in patients treated with MPC + HA was -27.6 at 12 months and -26.0 at 24 months from a baseline mean VAS of 60.4 (p=0.014 and p=0.036, respectively, compared with saline-treated controls). Patients who received MPCs alone had mean VAS reductions intermediate between saline and MPC + HA, indicating an additive role for HA carrier, likely by increasing targeting of mesenchymal stromal cells to inflammatory sites.⁶ The durable pain reductions observed over 24 months confirm outcomes from a prior randomized controlled trial which showed that the same dose and formulation of MPC + HA resulted in significantly greater reduction in pain, as measured by LS mean change in VAS from baseline, at both 12 months and 24 months compared with saline (p=0.018 and p=0.006, respectively), whereas HA alone was not significantly different from saline.¹

Figure 1: LS Mean VAS Low Back Pain Change from Baseline VAS of 60.4 – Entire Study (n=391)

Maximal pain reduction with MPC + HA was seen in the pre-specified subset of patients treated within a shorter duration of CLBP than the study's median of 68 months (n=194). Figure 2 shows the least-squared (LS) mean change from baseline in patients treated with MPC + HA was -36.9 at 12 months and -36.5 at 24 months ($p < 0.0001$ at both timepoints compared with saline-treated controls). Further, minimal to no pain (VAS ≤ 20) was seen in 60% of these patients treated with MPC + HA at 12 months and in 54% at 24 months ($p = 0.011$ and $p = 0.036$, respectively, compared to saline controls).

Figure 2: LS Mean VAS Low Back Pain Change from Baseline - Duration CLBP < Median (n=194)

Pre-specified measurements of function and disability showed that the EuroQoL 5-dimensional questionnaire (EQ-5D) Index appeared to be a more sensitive discriminator of treatment effect than the Oswestry Disability Index (ODI) in this patient population. In the population with shorter duration

of CLBP than the median for the study, MPC + HA improved function and disability compared with saline at both 12 and 24 months, as measured by either EQ-5D Index ($p=0.009$ and $p=0.020$, respectively) or ODI ($p=0.044$ and $p=0.059$, respectively). In these patients MPC + HA resulted in increased composite responder outcomes at 24 months of 50% reduction in pain and improvement in function as measured by either >0.03 EQ-5D Index or by >15 -point ODI ($p=0.04$ and $p=0.06$, respectively).

Population of Patients Taking Opioids

In the pre-specified population of opioid users at baseline ($n=168$), patients who received a single injection of MPC + HA had a significantly greater reduction in pain at all time-points (1, 3, 6, 12, 18 and 24 months) compared with saline controls ($p<0.05$ for all timepoints). Importantly, despite instructions to treating physicians and patients to not change any medications during the trial, by 24 months there was a 40% reduction in opioid use (as measured by morphine equivalent dose, MED) in patients treated with a single injection of MPC + HA ($p=0.03$). Conversely, more saline treated opioid users actually increased their daily MED opioid use over 24 months than those treated with MPC + HA (50% vs 13% at 24 months, $p=0.0009$).

By 24 months, 46% of patients treated with MPC + HA achieved 50% reduction in VAS together with opioid MED dose reduction compared with only 12% of saline controls ($p=0.004$), and 32% vs 12% ($p=0.05$) achieved a composite of 50% reduction in VAS and 15-point improvement in ODI together with opioid reduction. Treatment with MPC + HA resulted in a 5-fold increase in the proportion of patients achieving a composite of 50% reduction in pain and an EQ-5D Index response at both 12 and 24 months (33% vs 6%, $p=0.006$) while at the same time reducing opioid use.

Mesoblast Chief Medical Officer Dr Fred Grossman said: "These results show very meaningful improvements in debilitating CLBP for at least two years after a single injection of our anti-inflammatory mesenchymal precursor cells (MPCs) in an outpatient procedure. On the basis of the Phase 3 trial results, we intend to meet with the FDA and discuss potential pathways towards approval for rexlemestrocel-L, including as an opioid sparing treatment in patients with DDD."

Conference Call

There will be a webcast today beginning at 9.30am AEDT (Thursday, February 11); 5.30pm EST (Wednesday, February 10, 2021). It can be accessed via

About Chronic Low Back Pain due to Degenerative Disc Disease

Chronic low back pain (CLBP) affects approximately 10-15% of the adult population, equivalent to more than 30 million people in the United States and almost 40 million people across the EU³. Degenerative disc disease (DDD) causing discogenic pain is the most common etiology of CLBP in adults.^{7,8} Over 7 million patients in each of the United States and E.U.5 are thought to suffer from CLBP caused by degenerative disc disease,⁷⁻⁹ a disease which involves inflammation and degeneration of the intervertebral discs due to various factors including age, trauma or genetic pre-disposition.

Back pain causes more disability than any other condition⁹ and inflicts substantial direct and indirect costs on the healthcare system⁹, including excessive use of opioids in this patient population. There are few treatment options for patients with CLBP who fail conservative therapy, including opioids, spinal injections and surgery (e.g., spinal fusion or total disk arthroplasty).¹⁰ More than 50% of US opioid prescriptions are for the treatment of CLBP,³⁻⁵ despite the fact that opioids are associated with serious and potentially life-threatening side effects and have not demonstrated efficacy in the treatment of CLBP.^{5,11,12} In 2018, more than 67,000 drug overdose deaths occurred in the United States¹³ of which almost 47,000 (70%) were opioid related.

About Mesoblast

Mesoblast is a world leader in developing allogeneic (off-the-shelf) cellular medicines for the treatment of severe and life-threatening inflammatory conditions. The Company has leveraged its proprietary

mesenchymal lineage cell therapy technology platform to establish a broad portfolio of late-stage product candidates which respond to severe inflammation by releasing anti-inflammatory factors that counter and modulate multiple effector arms of the immune system, resulting in significant reduction of the damaging inflammatory process.

Mesoblast has a strong and extensive global intellectual property portfolio with protection extending through to at least 2040 in all major markets. The Company's proprietary manufacturing processes yield industrial-scale, cryopreserved, off-the-shelf, cellular medicines. These cell therapies, with defined pharmaceutical release criteria, are planned to be readily available to patients worldwide.

Mesoblast has completed Phase 3 trials of rexlemestrocel-L for advanced chronic heart failure and chronic low back pain. Remestemcel-L is being developed for inflammatory diseases in children and adults including steroid refractory acute graft versus host disease and moderate to severe acute respiratory distress syndrome. Two products have been commercialized in Japan and Europe by Mesoblast's licensees, and the Company has established commercial partnerships in Europe and China for certain Phase 3 assets.

Mesoblast has locations in Australia, the United States and Singapore and is listed on the Australian Securities Exchange (MSB) and on the Nasdaq (MESO). For more information, please see www.mesoblast.com, LinkedIn: Mesoblast Limited and Twitter: @Mesoblast
