

Hualilan Delivers 6m at 89.3 g/t Au, 88.5 g/t Ag, 3.4% Zn

Highlights

- Outstanding first results from Main Manto rock saw channel sampling including (Refer Table 2):
 - 71.0m at 10.8 g/t AuEq² - 9.2 g/t Au, 22.5 g/t Ag, 3.0% Zn in combined Zone 1 and Zone 2 including intervening lower grade mineralisation in RNNV10_04;
- Zone 1:
 - 26.0m at 24.7 g/t AuEq² - 21.2 g/t Au, 28.4 g/t Ag, 7.2% Zn in RNNV10_04 including;
 - 6.0m at 91.9 g/t AuEq² - 89.3 g/t Au, 88.5 g/t Ag, 3.4% Zn, and
 - 5.0m at 24.5 g/t AuEq² - 20.5g/t Au, 53.1g/t Ag, 7.5% Zn in RNNV10_03;
 - Zone 1 true width is 9 - 10 metres immediately below surface
- Zone 2:
 - 17.0m at 7.1 g/t AuEq² - 5.9 g/t Au, 45.2 g/t Ag, 1.5% Zn in RNNV10_04 and;
 - 3.0m at 23.8 g/t AuEq² - 20.9g/t Au, 92.4g/t Ag, 3.9% Zn in RNNV10_08;
 - Zone 2 true width is 7 - 8 metres located 23 metres below surface
- Zone 3
 - 29m at 2.4 g/t AuEq² - 0.8g/t Au, 22.7 g/t Ag, 2.9% Zn in RNNV10_04 and;
 - 9.0m at 6.2 g/t AuEq² - 1.5g/t Au, 100g/t Ag, 7.2% Zn in RNNV10_06;
 - Zone 3 true width is approximately 12 metres, located 45 metres below surface
- Rock saw cut, representative, channel sampling has identified high-grade zones that were previously untested and the results correlate well with high-grade drill intercepts down dip.
- The program was designed to provide data for inclusion of the near surface mineralisation, originally defined by underground sampling, in a JORC resource estimate.
- Results suggest the mineralisation is thicker than expected and that the historical selective channel sampling has missed much broader zones of near surface mineralisation.
- This is a significant step supporting CEL's strategy to deliver a high grade shallow resource that should enable a low capex, high margin starter mining operation.

Commenting on the results, CEL Managing Director, Mr Kris Knauer, said

"These near surface results are exceptional and continue to reinforce our belief we have a significant gold system at our flagship Hualilan Gold Project in Argentina. We can see that:

- *mineralisation is wider than expected near surface; and has;*
- *a strong correlation with high-grade drill hole results down dip; and*
- *historical sampling based on the presence of visual sulphides missed broader near surface zones.*

This is a further important step in delivering on our strategy to become a globally significant gold producer initially targeting high grade shallow mineralisation.

Challenger Exploration (ASX: CEL) ("CEL" the "Company") is pleased to announce first results from the underground channel sampling at the Company's Hualilan Gold project in San Juan province, Argentina.

The channel sampling program has been designed to allow the inclusion of the component of the historical high-grade mineralisation which is up-dip of the Company's drilling in a resource estimate that can be reported according to JORC. This includes the majority of the mineralisation within 40 metres of surface and the extensions of mineralisation up into the hills at Cerro Norte and Cerro Sur. In historical foreign (non JORC compliant) resource calculations this mineralisation was included based on the results of underground mapping and selective channel sampling. Importantly, this near surface component of the mineralisation generally exhibits high-grades.

The sampling was done using a rock saw to cut and recover a continuous channel measuring approximately 40cm x 40cm, with sample weight averaging 4.8 kg per metre. Samples were logged, and submitted for assay with QAQC samples (blanks and standards) using the same procedure as drill core. The channel sample is analogous to a drill core sample. It is expected that the data can be incorporated into a resource estimation in the same way as drilling results.

The first channel samples were taken from the Main Decline at Cerro Norte and are the first known continuous sampling undertaken down the Decline. Sampling was also undertaken across sections of the roof of the Decline and vertically on the Decline walls to better define the mineralisation in three dimensions. Selected results are shown below (Table 1) with complete results are provided in Table 2. Importantly, several of the channels started and/or ended in mineralisation.

Drill Hole (#)	From (m)	To (m)	Total (m)	Gold (g/t)	Ag (g/t)	Zn (%)	Au Equiv (g/t)	Comments

Table 1 - Selected results from Channel Sampling in main Decline at Cerro Norte

The Channel Sampling program has been significantly expanded given the highly encouraging results including:

- The high-grades encountered which indicate that the near surface component of the historical mineralisation tends to contain high grades
- The channels defining the up-dip extensions of high-grade shoots identified in CEL drilling

- The confirmation of broad zones of mineralisation that were missed by the selective historical sampling which may be important in the context of potential open pit mining.

DISCUSSION OF RESULTS

At Cerro Norte the Main Manto covers at least 400 metres of strike (north-south), dips at 30-40 degrees to the west and is generally 2-10 metres thick. The Main Manto includes a number of thicker and higher-grade plunging shoots within its mineralised envelope which plunge to the south west. The Main Decline, constructed in 1999 and rehabilitated for the channel sampling, intersects several high-grade shoots of the Main Manto enabling determination of the true width and orientation of these shoots.

Figures 1 and 2 show the location of the higher-grade shoots intersected and the underground Channel samples projected onto a Long Section and Plan View. The figures also include the historical underground sampling which was undertaken prior to the decline and the historical underground workings.

Main channel down the decline

The main channel sample was taken down the western wall of the decline (RNNV10_04) and extended for 350 metres from the start of the decline. It defines three main high-grade plunging zones within the main manto at Cerro Norte which occur over approximately 250 metres of strike extent of the Main Manto.

The broad zone of mineralisation encountered in channel RNNV10_04 of **71.0 metres at 10.7 g/t AuEq (9.2 g/t gold, 22.5 g/t silver, 3.0 % zinc)** from the decline entrance consists of two higher-grade plunging shoots with lower grade mineralisation between them. The upper shoot returned **26.0 metres (true thickness 9-10 metres) at 24.7 g/t AuEq (21.2 g/t gold, 28 g/t silver, 7.2 % zinc)** from near the decline entrance, with the lower shoot recording and **17.0 metres (true thickness 7-8 metres) at 7.1 g/t AuEq (5.9 g/t Au, 45 g/t Ag, 1.5 % zinc)**.

There is an exceptionally high grade component within the upper shoot which returned **6.0 metres at 91.9 g/t AuEq (89.3 g/t gold, 88.5 g/t silver, 3.5 % zinc)**. The two upper zones intersected in the decline are interpreted as the up-plunge extension of mineralisation intersected in the Company's drill holes including GNDD-003 (6.1m at 34.6 g/t Au, 21.9 g/t Ag, 2.9% Zn), GNDD035 (5.8m at 9.5 g/t Au, 28.7 g/t Ag, 3.5% Zn), GNRC098 (8m at 4.9 g/t Au, 4.5 g/t Ag, 0.8% Zn) and GNDD141 (6.5m at 14.3 g/t Au, 43.6 g/t Ag, 3.4% Zn). These drill holes were collared 60 to 160 metres away which confirms the continuity of the high-grade plunging shoots.

Chanel RNNV10_08 was taken on the opposite side of the decline approximately midway between the two main shoots. This returned of **3.0 metres at 23.8 g/t AuEq (20.9 g/t gold, 92.4 g/t silver, 3.9 % zinc)** including **2.0 metres at 35.4 g/t AuEq (31.2 g/t gold, 136.9 g/t silver, 5.6 % zinc)** with the channel open in both directions. It is postulated this may be another unrecognised high grade shoot which was only encountered in the eastern wall as the majority of the high-grade mineralisation lies above the decline.

Channel RNNV10_03 which returned **5.0 metres at 24.5 g/t AuEq (21.2 g/t Au, 28 g/t Ag, 7.2 % zinc)** including **4.0 metres at 30.0 g/t AuEq (25.6 g/t Au, 60.5 g/t Ag, 8.3 % zinc)** was taken across the roof of the decline and was oriented perpendicular to channel RNNV10_04 near the first zone. As such the channel sample would be expected to start and end in mineralisation, as it did, with the highest 1 metre split of 73.7 g.t gold, 58.0 g.t silver and 1% zinc being the last sample in the channel.

The third shoot down the decline returned of **33.0 metres (true thickness approximately 12 metres) at 2.1 g/t AuEq (0.7 g/t gold, 20.6 g/t silver, 2.6 % zinc)** from 190 metres with a part channel of the other decline wall returning **10.0 metres at 5.7 g/t AuEq (1.4 g/t gold, 90.9 g/t silver, 7.2 % zinc)** which started and ended in mineralisation. This mineralisation has also been intersected in GNDD190 (assay pending)

The channel sampling also intersected additional lower-grade zones of mineralisation further down the decline including **4 meters at 1.2 g/t AuEq (1.2 g/t gold, 1.5 g/t silver and 0.1 % zinc)** at the Sanchez Fault zone

CONCLUSIONS

The Main Decline drifts (is oriented) at 8-10 degrees northwards and was originally driven in the footwall of the Main Manto mineralisation rather than be developed on the mineralisation. The intersection of the high-grade mineralisation in the decline likely indicates the Main Manto mineralisation at Cerro Norte is thicker than historically believed.

The high-grade results and broader zones of mineralisation in the channel sampling in the Main Decline was not anticipated by the Company as much of the mineralisation was not visible until after the walls were cleaned and thus was not noted visually. This further supports the view that the selective historical channel sampling, which was done based on the presence of visual sulphides, has missed much broader zones of mineralisation near surface. The presence of broad zones of remnant lower grade mineralisation surrounding the higher-grade mineralisation is encouraging in the context of potential exploitation by open pit mining.

With the exception of the 6 metre high grade zone, which contains the highest grades recorded to date at Hualilan including **1 metre at 315 g/t gold** and **1 metre at 152 g/t gold**, the grades encountered are in line with the historical resource. Recognising that this near surface zone of the historical resource which was defined by channel sampling is the higher-grade component of the historical resource.

The figures show the historical underground workings which are predominantly constrained to within 75 metres sub-surface and, according to the historical records, generally recovered hand-sorted grades above 20 g/t gold only where visible gold was encountered. The CEL sampling demonstrates high grades remain in the workings where no visible gold was observed in addition to lower grade mineralisation not recognised in historical sampling. As can be seen, the historical workings are limited in size and it is believed that historical mining extracted less than 100,000-200,000 ounces in total across Cerro Sur and Cerro Norte.

See below for information regarding AuEq's reported under the JORC Code.

² Gold Equivalent (AuEq) values - Requirements under the JORC Code

- Assumed commodity prices for the calculation of AuEq is Au US\$1780 Oz, Ag US\$24 Oz, Zn US\$2,800 /t
- Metallurgical recoveries for Au, Ag and Zn are estimated to be 89%, 84% and 79% respectively (see **JORC Table 1 Section 3 Metallurgical assumptions**) based on metallurgical test work.
- The formula used: $AuEq (g/t) = Au (g/t) + [Ag (g/t) \times (24/1780) \times (0.84/0.89)] + [Zn (\%) \times (28.00 \times 31.1/1780) \times (0.79/0.89)]$
- CEL confirms that it is the Company's opinion that all the elements included in the metal equivalents calculation have a reasonable potential to be recovered and sold.

The channel sampling appears to have missed one higher-grade shoot which was defined by historical underground sampling in the old workings prior to the installation of the decline. It is believed this shoot is present however the Decline passed over the top of this shoot.

NEXT STEPS

The results demonstrate the importance of the underground Channel Sampling program to:

- Facilitate the inclusion of much of the shallow historical mineralisation into a resource estimate that can be reported according to JORC; and
- Define broader zones of lower grade near surface mineralisation missed by the selective historical sampling;

Accordingly, the program of underground Channel Sampling has been extended to cover all of the safely accessible historic underground shafts, adits, and tunnels at both Cerro Norte and Cerro Sur. Channel sampling in some of the tunnels which were cut by the Main Decline, and other historical workings at Cerro Norte and Muchilera (Cerro Sur) has been completed and samples submitted for analysis.

29 Jan 2021 - DRILLING CONTINUES TO EXTEND THE BOUNDARIES OF THE HIGH-GRADE MINERALISATION AT CHALLENGERS FLAGSHIP HUALILAN GOLD PROJECT

About Challenger Exploration

Challenger Exploration Limited's (ASX: CEL) aspiration is to become a globally significant gold producer. The Company is developing two complementary gold/copper projects in South America. The strategy for the Hualilan Gold project is for it to provide a high-grade low capex operation in the near term. This underpins CEL with a low risk, high margin source of cashflow while it prepares for a much larger bulk gold operation in Ecuador.

1. **Hualilan Gold Project**, located in San Juan Province Argentina, is a near term development opportunity. It has extensive historical drilling with over 150 drill-holes and a non-JORC historical resource ⁽¹⁾ of 627,000 Oz @ 13.7 g/t gold which remains open in most directions. The project was locked up in a dispute for the past 15 years and as a consequence had seen no modern exploration until CEL acquired the project in 2019. Results from CEL's first drilling program included 6.1m @ 34.6 g/t Au, 21.9 g/t Ag, 2.9% Zn, 6.7m @ 14.3 g/t Au, 140 g/t Ag, 7.3% Zn and 10.3m @ 10.4 g/t Au, 28 g/t Ag, 4.6% Zn. This drilling intersected high-grade gold over almost 2 kilometres of strike and extended the known mineralisation along strike and at depth in multiple locations. Recent drilling has demonstrated this high-grade skarn mineralisation is underlain by a significant intrusion-hosted gold system with intercepts including 116m at 1.0 g/t Au, 4.0 g/t Ag, 0.2% Zn and 39.0m at 5.5 g/t Au, 2.0 g/t Ag, 0.3% Zn in porphyry dacites. CEL's current program includes 45,000 metres of drilling, metallurgical test work of key ore types, and an initial JORC Compliant Resource and PFS.
2. **El Guayabo Gold/Copper Project** covers 35 sqkms in southern Ecuador and was last drilled by Newmont Mining in 1995 and 1997 targeting gold in hydrothermal breccias. Historical drilling has demonstrated potential to host significant gold and associated copper and silver mineralisation. Historical drilling has returned a number of intersections including 156m @ 2.6 g/t Au, 9.7 g/t Ag, 0.2% Cu and 112m @ 0.6 % Cu, 0.7 g/t Au, 14.7 g/t which have never been followed up. The Project has multiple targets including breccia hosted mineralisation, an extensive flat lying late stage vein system and an underlying porphyry system target neither of which has been drill tested. CEL's first results confirm the discovery of large-scale gold system with over 250 metres of bulk gold mineralisation encountered in drill hole ZK-02 which contains a significant high-grade core of 134m at 1.0 g/t gold and 4.1 g/t silver including 63m at 1.6 g/t gold and 5.1 g/t silver.

^{#1} For details of the foreign non-JORC compliant resource and to ensure compliance with LR 5.12 please refer to the Company's ASX Release dated 25 February 2019. These estimates are foreign estimates and not reported in accordance with the JORC Code. A competent person has not done sufficient work to clarify the foreign estimates as a mineral resource in accordance with the JORC Code. It is uncertain that following evaluation and/or further exploration work that the foreign estimate will be able to be reported as a mineral resource. The company is not in possession of any new information or data relating to the foreign estimates that materially impact on the reliability of the estimates that materially impacts on the reliability of the estimates or CEL's ability to verify the foreign estimates estimate as minimal resources in accordance with Appendix 5A (JORC Code). The company confirms that the supporting information provided in the initial market announcement on February 25, 2019 continues to apply and is not materially changed.

Competent Person Statement – Exploration results

The information that relates to sampling techniques and data, exploration results and geological interpretation has been compiled Dr Stuart Munroe , BSc (Hons), PhD (Structural Geology), GDip (AppFin&Inv) who is a full-time employee of the Company. Dr Munroe is a Member of the AusIMM. Dr Munroe has over 20 years' experience in the mining and metals industry and qualifies as a Competent Person as defined in the JORC Code (2012).

Dr Munroe has sufficient experience of relevance to the styles of mineralisation and the types of deposits under consideration, and to the activities undertaken, to qualify as a Competent Person as defined in the 2012 Edition of the Joint Ore Reserves Committee (JORC) Australasian Code for Reporting of Exploration Results. Dr Munroe consents to the inclusion in this report of the matters based on information in the form and context in which it appears. The Australian Securities Exchange has not reviewed and does not accept responsibility for the accuracy or adequacy of this release.

Competent Person Statement – Foreign Resource Estimate

The information in this release provided under ASX Listing Rules 5.12.2 to 5.12.7 is an accurate representation of the available data and studies for the material mining project. The information that relates to Mineral Resources has been compiled by Dr Stuart Munroe , BSc (Hons), PhD (Structural Geology), GDip (AppFin&Inv) who is a full-time employee of the Company. Dr Munroe is a Member of the AusIMM. Dr Munroe has over 20 years' experience in the mining and metals industry and qualifies as a Competent Person as defined in the JORC Code (2012).

Dr Munroe and has sufficient experience which is relevant to the style of mineralisation and type of deposits under consideration to qualify as Competent Person as defined in the 2012 Edition of the JORC Code for Reporting of, Mineral Resources and Ore Reserves. Dr Munroe consents to the inclusion in this report of the matters based on information in the form and context in which it appears. The Australian Securities Exchange has not reviewed and does not accept responsibility for the accuracy or adequacy of this release.

JORC Code, 2012 Edition – Table 1 report template

Section 1 Sampling Techniques and Data -Hualilan Project

(Criteria in this section apply to all succeeding sections.)

Criteria	JORC Code explanation	Commentary
Sampling techniques	- <i>Nature and quality of sampling (eg cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling.</i> - <i>Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.</i> - <i>Aspects of the determination of mineralisation that are Material to the Public Report.</i> - <i>In cases where 'industry standard' work has been done this would be relatively simple (eg 'reverse circulation drilling was used to obtain 1 m samples from which 3 kg was pulverised to produce a 30 g charge for fire assay'). In other cases, more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (eg submarine nodules) may warrant disclosure of detailed information.</i>	For historic exploration data, there is little information provided by previous explorers to detail sampling techniques. Drill core was cut with a diamond saw longitudinally and one half submitted for assay. Assay was generally done for Au. In some drill campaigns, Ag and Zn were also analysed. There is limited multielement data available. No information is available for RC drill techniques and sampling. For CEL drilling, diamond core (HQ3) was cut longitudinally on site using a diamond saw. Samples lengths are from 0.5m to 2.0m in length (average 1m), taken according to lithology, alteration, and mineralization contacts. For CEL reverse circulation (RC) drilling, 2-4 kg sub-samples from each 1m drilled are collected from a face sample recovery cyclone mounted on the drill machine. CEL channel samples are cut into underground or surface outcrop using a hand-held diamond edged cutting tool. Parallel saw cuts 3-5cm apart are cut 2-4cm deep into the rock which allows for the extraction of a representative sample using and hammer and chisel. The sample is collected onto a plastic mat and collected into a sample bag. Core and channel samples were crushed to approximately 85% passing 2mm. A 500g or a 1 kg sub-sample was taken and pulverized to 85% passing 75µm. A 50g charge was analysed for Au by fire assay with AA determination. Where the fire assay grade is > 10 g/t gold, a 50g charge was analysed for Au by Fire assay with gravimetric determination. A 10g charge was analysed for 48 elements by 4-acid digest and ICP-MS determination. Elements determined were Ag, As, Ba, Be, Bi, Ca, Ce, Co, Cr, Cs, Cu, Fe, Ga, Ge, Hf, In, K, La, Li, Mg, Mn, Mo, Na, Nb, Ni, P, Pb, Rb, Re, S, Sb Sc, Se, Sn, Sr, Ta, Te, Th, Ti, Tl, U, V, W, Y, Zn and Zr. Ag > 100 g/t, Zn, Pb and Cu > 10,000 ppm and S > 10% were re-analysed by the same method using a different calibration. Sample intervals were selected according to geological boundaries. There was no coarse gold observed in any of the core or channel samples.
Drilling techniques	- <i>Drill type (eg core, reverse circulation, open-hole hammer, rotary air blast, auger, Bangka, sonic, etc) and details (eg core diameter, triple or standard tube, depth of diamond tails, face-sampling bit or other type, whether core is oriented and if so, by what method, etc).</i>	Collar details for diamond core drilling (DD) and reverse circulation (RC) historic drilling campaigns is provided below from archival data cross checked with drill logs and available plans and sections where available. Collars shown below are in WGS84, zone 19s which is the standard projection used by CEL for the Project. Collar locations have been check surveyed using differential GPS (DGPS) by CEL to verify if the site coincides with a marked collar or tagged drill site. In most cases the drill collars coincide with

CEL drilling of HQ3 core (triple tube) was done using various truck and track mounted drill machines that are operated by various Argentinian drilling companies based in Mendoza and San Juan. The core has not been oriented.									
CEL drilling of reverse circulation (RC) drill holes was done using a track-mounted LM650 universal drill rig set up for reverse circulation drilling. Drilling is being done using a 5.25 inch hammer bit.									
Collar details for DD drill holes and RC drill holes completed by CEL are shown below in WGS84, zone 19s projection. Collar locations for drill holes to GNDD205 are surveyed using DGPS. Collar location from GNDD206 are surveyed with a handheld GPS to be followed up with DGPS.

Drill sample recovery	- Method of recording and assessing core and chip sample recoveries and results assessed. - Measures taken to maximise sample recovery and ensure representative nature of the samples. - Whether a relationship exists between sample recovery and grade and whether sample bias may have occurred due to preferential loss/gain of fine/coarse material.	Drill core is placed into wooden boxes by the drillers and depth marks are indicated on wooden blocks at the end of each run. These depths are reconciled by CEL geologists when measuring core recovery. Triple tube drilling has been being done by CEL to maximise core recovery. RC sub-samples are collected from a rotary splitter mounted to the face sample recovery cyclone. A 2-4 kg sub-samples is collected for each metre of RC drilling. Duplicate samples are taken at the rate of 1 every 25-30 samples using a riffle splitter to split out a 2-4 kg sub-sample. The whole sample recovered is weighed to measure sample recovery and consistency in sampling. A possible relationship has been observed between historic sample recovery and Au Ag or Zn grade whereby low recoveries have resulted in underreporting of grade. Insufficient information is not yet available to more accurately quantify this. Core recovery is influenced by the intensity of natural fracturing in the rock. A positive correlation between recovery and RQD has been observed. The fracturing is generally post mineral and not directly associated with the mineralisation.
Logging	- Whether core and chip samples have been geologically and geotechnically logged to a level of detail to support appropriate Mineral Resource estimation mining studies and metallurgical studies. - Whether logging is qualitative or quantitative in nature. Core (or costean channel etc) photography. - The total length and percentage of the relevant intersections logged.	Detailed logs are available for most of the historical drilling. Some logs have not been recovered. No core photographs from the historic drilling have been found. No drill core has survived due to poor storage and neglect. No RC sample chips have been found. For CEL drilling, all the core is logged for recovery RQD weathering lithology alteration mineralization and structure to a level that is suitable for geological modelling resource estimation and metallurgical test work. RC drill chips are logged for geology, alteration and mineralisation. Where possible logging is quantitative. Geological logging is done in MS Excel in a format that can readily be transferred to a database which holds all drilling logging sample and assay data.

Criteria	JORC Code explanation	Commentary																																																																																										
Sub-sampling techniques and sample preparation	- If core whether cut or sawn and whether quarter half or all core taken.	Competent drill core is cut longitudinally using a diamond saw for sampling of ½ the core. Soft core is split using a wide blade chisel or a manual core split press. The geologist logging the core indicates on the drill core where the saw cut is to be made to ensure half-core sample representivity.																																																																																										
	- If non-core whether riffled tube sampled rotary split etc and whether sampled wet or dry.																																																																																											
	- For all sample types the nature quality and appropriateness of the sample preparation technique.	Sample intervals are selected based on lithology alteration and mineralization boundaries. Sample lengths average 1.38m. No second-half core samples have been submitted. The second half of the core samples has been retained in the core trays for future reference.																																																																																										
	- Quality control procedures adopted for all sub-sampling stages to maximise representivity of samples.																																																																																											
	- Measures taken to ensure that the sampling is representative of the in-situ material collected including for instance results for field duplicate/second-half sampling.	From hole GNDD073, duplicate diamond core samples have been collected for every 25-30m drilled. The duplicate diamond core samples are ¼ core samples. Duplicate core sample results and correlation plots (log scale for Au, Ag and Zn) are shown below:

JORC Code explanation

Commentary

RC sub-samples over 1m intervals are collected at the drill site from a cyclone mounted on the drill rig. A duplicate RC sample is collected for every 25-30m drilled.

The duplicate RC sample results and correlation plots (log scale for Au, Ag and Zn) are shown below:

	n	RSQ	mean		median		variance	
			original	duplicate	original	duplicate	original	duplicate
Au (ppm)	85	0.799	0.101	0.140	0.017	0.016	0.041	0.115
Ag (ppm)	85	0.691	1.74	2.43	0.59	0.58	13.59	64.29
Cd (ppm)	85	0.989	15.51	16.34	0.41	0.44	4189	4737
Cu (ppm)	85	0.975	47.74	53.86	5.80	5.70	2.4E+04	3.1E+04

Criteria	JORC Code explanation	Commentary
		 2020 Hualilan RC - Duplicate Samples - Au (ppm) 2020 Hualilan RC - Duplicate Samples - Ag (ppm) 2020 Hualilan RC - Duplicate Samples - Zn (ppm) CEL samples have been submitted to the MSA laboratory in San Juan and the ALS laboratory in Mendoza for sample preparation. The sample preparation technique is considered appropriate for the style of mineralization present in the Project. Sample sizes are appropriate for the mineralisation style and grain size of the deposit. 12 duplicate channel samples have been collected. The data is not yet statistically significant to allow a discussion of the significance of the results.
Quality of assay data and laboratory tests	- <i>The nature quality and appropriateness of the assaying and laboratory procedures used and whether the technique is considered partial or total.</i> - <i>For geophysical tools spectrometers handheld XRF instruments etc the parameters used in determining the analysis including instrument make and model reading times calibrations factors applied and their derivation etc.</i> - <i>Nature of quality control procedures adopted (eg standards blanks duplicates external laboratory checks) and whether acceptable levels of accuracy (i.e. lack of bias) and precision have been established.</i>	The MSA laboratory used for sample preparation in San Juan has been inspected by Stuart Munroe (Exploration Manager) and Sergio Rotondo (COO) prior to any samples being submitted. The laboratory procedures are consistent with international best practice and are suitable for samples from the Project. The ALS laboratory in Mendoza has not yet been inspected by CEL representatives. Internal laboratory standards were used for each job to ensure correct calibration of elements. CEL submit blank samples (cobble and gravel material from a quarry nearby to Las Flores San Yuan) to both the MSA laboratory and the ALS laboratory which were strategically placed in the sample sequence immediately after samples that were suspected of containing high grade Au Ag Zn or Cu to test the lab preparation contamination procedures. The values received from the blank samples suggest rare cross contamination of samples during sample preparation. 13 blank samples have been submitted with the channel samples where final results been received. The blank sample results are consistent with the blank results submitted with the drill core samples and no unexpected results have been returned.

JORC Code explanation

Commentary

For GNDD001 – GNDD010 samples analysed by MSA in 2019, three different Certified Standard Reference pulp samples (CRM) with known values for Au Ag Pb Cu and Zn have been submitted with samples of drill core to test the precision and accuracy of the analytic procedures and determination of the MSA laboratory in Canada. Two of the standards were only used 4 times each and the third . 26 reference analyses were analysed in the samples submitted in 2019. For CRM 1 one sample returned an Au value > 2 standard deviations (SD) above the certified value. For CRM 2 one sample returned an Au value < 2SD below the certified value. For CRM 3 (graphs below) one sample returned a Cu value > 2SD above the certified value. All other analyses are within 2SD of the expected value. The standards demonstrate suitable precision and accuracy of the analytic process. No systematic bias is observed.

For drill holes from GNDD011 and unsampled intervals from the 2019 drilling, six different Certified Standard Reference pulp samples (CRM) with known values for Au Ag Fe S Pb Cu and Zn have been submitted with samples of drill core to test the precision and accuracy of the analytic procedures of both the MSA and ALS. In the results received to date there has been no observed bias in results of the CRM.

Criteria

JORC Code explanation

Commentary

The standards demonstrate suitable precision and accuracy of the analytic process. No systematic bias is observed. A summary of the standard deviations from the expected values for CRM's used is summarised below. Generally, an average of standard deviations close to zero indicates a high degree of accuracy and a low range of standard deviations with a low fail count indicates a high degree of precision. 11 standards (CRM) have been submitted with the channel samples. The results are consistent with CRM submitted with drill core samples.

Verification of sampling and assaying

- The verification of significant intersections by either independent or alternative company personnel.
- The use of twinned holes.
- Documentation of primary data entry procedures data verification data storage (physical and electronic) protocols.
- Discuss any adjustment to assay data.

Repeat sampling of 186 coarse reject samples from 2019 drilling has been done to verify sampling. Original samples were from the 2019 DD drilling which were analysed by MSA (San Juan preparation and Vancouver analysis). Repeat samples were analysed by ALS (Mendoza preparation and Vancouver analysis). The repeat analysis technique was identical to the original. The repeat analyses correlate very closely with the original analyses providing a high confidence in the sample preparation and analysis from MSA and ALS. A summary of the results for the 186 sample pairs for key elements is provided below:

Mean

Median

Location of data points	- Accuracy and quality of surveys used to locate drill holes (collar and down-hole surveys) trenches mine workings and other locations used in Mineral Resource estimation. - Specification of the grid system used. - Quality and adequacy of topographic control.	Following completion of drilling collars are surveyed using a differential GPS (DGPS) relative into the Argentinian SGM survey. The locations have been surveyed in POSGAR 2007 zone 2 and converted to WGS84 UTM zone 19s. Following completion of the channel sampling, the location of the channel samples taken underground is surveyed from a survey mark at the entrance to the underground which is located using differential GPS.

Criteria	JORC Code explanation	Commentary
		The drill machine is set-up on the drill pad using hand-held equipment according to the proposed hole design. Diamond core drill holes are surveyed at 30-40m intervals down hole using a Reflex tool. RC drill holes are surveyed down hole every 10 metres using a gyroscope to avoid magnetic influence from the drill rods. All current and previous drill collar sites Minas corner pegs and strategic surface points have been surveyed using DGPS to provide topographic control for the Project.
Data spacing and distribution	- <i>Data spacing for reporting of Exploration Results.</i> - <i>Whether the data spacing and distribution is sufficient to establish the degree of geological and grade continuity appropriate for the Mineral Resource and Ore Reserve estimation procedure(s) and classifications applied.</i> - <i>Whether sample compositing has been applied.</i>	No regular drill hole spacing has been applied across the Project, although a nominal 40m x 40m drill spacing is being applied to infill and extension drilling where appropriate. The current drilling is designed to check previous exploration, extend mineralisation along strike, and provide some information to establish controls on mineralization and exploration potential. No Mineral Resource Estimate to JORC 2012 reporting standards has been made at this time. Samples have not been composited.
Orientation of data in relation to geological structure	- <i>Whether the orientation of sampling achieves unbiased sampling of possible structures and the extent to which this is known considering the deposit type.</i> - <i>If the relationship between the drilling orientation and the orientation of key mineralised structures is considered to have introduced a sampling bias this should be assessed and reported if material.</i>	As far as is currently understood the orientation of sampling achieves unbiased sampling of structures and geology controlling the mineralisation. Drilling has been designed to provide an unbiased sample of the geology and mineralisation targeted.
Sample security	- <i>The measures taken to ensure sample security.</i>	Samples were under constant supervision by site security, senior personnel and courier contractors prior to delivery to the preparation laboratory in San Juan or Mendoza.
Audits or reviews	- <i>The results of any audits or reviews of sampling techniques and data.</i>	There has not yet been any independent reviews of the sampling techniques and data.

Section 2 Reporting of Exploration Results

(Criteria listed in the preceding section also apply to this section.)

Criteria	JORC Code explanation	Commentary																																																																														
Mineral tenement and land tenure status	- Type reference name/number location and ownership including agreements or material issues with third parties such as joint ventures partnerships overriding royalties native title interests historical sites wilderness or national park and environmental settings. - The security of the tenure held at the time of reporting along with any known impediments to obtaining a licence to operate in the area.	The current Hualilan project comprises 15 Minas (equivalent of mining leases) and 2 Demasias (mining lease extensions). This covers approximately 4 km of strike and includes all of the currently defined mineralization. There are no royalties on the project. CEL is earning a 75% interest in the Project by funding exploration to a Definitive Feasibility Study (DFS). <i>Granted mining leases (Minas Otorgadas) at the Hualilan Project</i> <table><tr><th>Name</th><th>Number</th><th>Current Owner</th><th>Status</th><th>Grant Date</th><th>Area (ha)</th></tr><tr><td colspan="6">Cerro Sur</td></tr><tr><td>Divisadero</td><td>5448-M-1960</td><td>Golden Mining S.R.L.</td><td>Granted</td><td>30/04/2015</td><td>6</td></tr><tr><td>Flor de Hualilan</td><td>5448-M-1960</td><td>Golden Mining S.R.L.</td><td>Granted</td><td>30/04/2015</td><td>6</td></tr><tr><td>Pereyra y Aciar</td><td>5448-M-1960</td><td>Golden Mining S.R.L.</td><td>Granted</td><td>30/04/2015</td><td>6</td></tr><tr><td>Bicolor</td><td>5448-M-1960</td><td>Golden Mining S.R.L.</td><td>Granted</td><td>30/04/2015</td><td>6</td></tr><tr><td>Sentazon</td><td>5448-M-1960</td><td>Golden Mining S.R.L.</td><td>Granted</td><td>30/04/2015</td><td>6</td></tr><tr><td>Muchilera</td><td>5448-M-1960</td><td>Golden Mining S.R.L.</td><td>Granted</td><td>30/04/2015</td><td>6</td></tr><tr><td>Magnata</td><td>5448-M-1960</td><td>Golden Mining S.R.L.</td><td>Granted</td><td>30/04/2015</td><td>6</td></tr><tr><td>Pizarro</td><td>5448-M-1960</td><td>Golden Mining S.R.L.</td><td>Granted</td><td>30/04/2015</td><td>6</td></tr><tr><td colspan="6">Cerro Norte</td></tr><tr><td>La Toro</td><td>5448-M-1960</td><td>CIA GPL S.R.L.</td><td>Granted</td><td>30/04/2015</td><td>6</td></tr><tr><td>La Puntilla</td><td>5448-M-1960</td><td>CIA GPL S.R.L.</td><td>Granted</td><td>30/04/2015</td><td>6</td></tr></table>	Name	Number	Current Owner	Status	Grant Date	Area (ha)	Cerro Sur						Divisadero	5448-M-1960	Golden Mining S.R.L. Criteria	JORC Code explanation	Commentary
		geology and sampling are currently being compiled and digitised as are sample data geological mapping trench data adit exposures and drill hole results. Geophysical surveys exist but have largely yet to be check located and digitised. Drilling on the Hualilan Project (Cerro Sur and Cerro Norte combined) extends to over 150 drill holes. The key historical exploration drilling and sampling results are listed below. - 1984 – Lixivia SA channel sampling & 16 RC holes (AG1-AG16) totalling 2040m - 1995 - Plata Mining Limited (TSE: PMT) 33 RC holes (Hua- 1 to 33) + 1500 samples - 1998 – Chilean consulting firm EPROM (on behalf of Plata Mining) systematic underground mapping and channel sampling - 1999 – Compania Mineral El Colorado SA (“CMEC”) 59 core holes (DDH-20 to 79) plus 1700m RC program - 2003 – 2005 – La Mancha (TSE Listed) undertook 7447m of DDH core drilling (HD-01 to HD-48) - Detailed resource estimation studies were undertaken by EPROM Ltda. (EPROM) in 1996 and CMEC (1999 revised 2000) both of which were written to professional standards and La Mancha 2003 and 2006. - The collection of all exploration data by the various operators was of a high standard and had appropriate sampling techniques intervals and custody procedures were used.
Geology	- <i>Deposit type geological setting and style of mineralisation.</i>	Mineralisation occurs in all rock types where it preferentially replaces limestone, shale and sandstone and occurs in fault zones and in fracture networks within dacitic intrusions. The mineralisation has previously been classified as a Zn-Cu distal skarn (or manto-style skarn) with vein-hosted Au-Ag mineralisation. It has been divided into three phases – prograde skarn retrograde skarn and a late quartz–galena event the evolution of the hydrothermal system and mineral paragenesis is the subject of more detailed geometallurgical work. Gold occurs in native form and as inclusions with sulphide and pyroxene. The mineralisation also commonly contains pyrite, chalcopryrite sphalerite and galena with rare arsenopyrite, pyrrhotite and magnetite. Mineralisation is either parallel to bedding in bedding-parallel faults, in veins or breccia matric within fractured dacitic intrusions, at lithology contacts or in east-west striking steeply dipping siliceous faults that cross the bedding at a high angle. The faults have thicknesses of 1–4 m and contain abundant sulphides. The intersection between the bedding-parallel mineralisation and east-striking cross veins seems to be important in localising the mineralisation.
Drill hole Information	- <i>A summary of all information material to the understanding of the exploration results including a tabulation of the following information for all</i>	The following significant intersections have been reported by previous explorers. A cut-off grade of 1 g/t Au equivalent has been used with up to 2m of internal diltion or a cut-off grade of 0.2 g/t Au equivalent and up to 4m of internal diltion has been allowed. No metallurcial or recovery factors have been used. Drill collar location

		(1) cut off 10 g/t Au equivalent									
		(2) cut off 0.2 g/t Au equivalent									
		NSI: no significant intersection									
Data aggregation methods	- In reporting Exploration Results weighting averaging techniques maximum and/or minimum grade truncations (eg cutting of high grades) and cut-off grades are usually Material and should be stated. - Where aggregate intercepts incorporate short lengths of high-grade results and longer lengths of low-grade results the procedure used for such aggregation should be stated and some typical examples of such aggregations should be shown in detail. - The assumptions used for any reporting of metal	Weighted average significant intercepts are reported to a gold grade equivalent (AuEq). Results are reported to cut-off grade of a 1.0 g/t Au equivalent and 10 g/t Au equivalent allowing for up to 2m of internal dilution between samples above the cut-off grade and 0.2 g/t Au equivalent allowing up to 6m of internal dilution between samples above the cut-off grade. The following metals and metal prices have been used to report gold grade equivalent: Au US\$ 1780 / oz Ag US\$24 /oz and Zn US\$ 2800 /t. Metallurgical recoveries for Au, Ag and Zn have been estimated from metallurgical test work completed by SGS Metallurgical Operations in Lakefield, Ontario using a combination of gravity and flotation of a combined metallurgical sample from 5 drill holes. Using data from the test results, and for the purposes of the AuEq calculation gold recovery is estimated at 89%, silver at 84% and zinc at 79%. Accordingly, the formula used is $AuEq (g/t) = Au (g/t) + [Ag (g/t) \times (24/1780) \times (0.84/0.89)] + [Zn (\%) \times (28.00 \times 31.1/1780) \times (0.79/0.89)]$.

Criteria	JORC Code explanation	Commentary
	<i>equivalent values should be clearly stated.</i>	Metallurgical test work and geological and petrographic descriptions suggest all the elements included in the metal equivalents calculation have a reasonable potential of eventual economic recovery. While Cu and Pb are reported in the table above, these metals are not used in the Au equivalent calculation at this early stage of the Project. No top cuts have been applied to the reported grades.
Relationship between mineralisation widths and intercept lengths	- <i>These relationships are particularly important in the reporting of Exploration Results.</i> - <i>If the geometry of the mineralisation with respect to the drill hole angle is known its nature should be reported.</i> - <i>If it is not known and only the down hole lengths are reported there should be a clear statement to this effect (eg 'down hole length true width not known').</i>	The mineralisation is moderately or steeply dipping and strikes NNE and ENE. For some drill holes, there is insufficient information to confidently establish the true width of the mineralized intersections at this stage of the exploration program. Apparent widths may be thicker in the case where bedding-parallel mineralisation may intersect ENE-striking cross faults and veins. Representative cross section interpretations have been provided with release of significant intersections to allow estimation of true widths from individual drill intercepts.
Diagrams	- <i>Appropriate maps and sections (with scales) and tabulations of intercepts should be included for any significant discovery being reported These should include but not be limited to a plan view of drill hole collar locations and appropriate sectional views.</i>	Representative maps and sections are provided in the body of report.
Balanced reporting	- <i>Where comprehensive reporting of all Exploration Results is not practicable representative reporting of both low and high grades and/or widths should be practiced to avoid misleading reporting of Exploration Results.</i>	All available data have been reported.
Other substantive exploration data	- <i>Other exploration data if meaningful and material should be reported including (but not limited to): geological observations; geophysical survey results; geochemical survey results; bulk samples – size and method of treatment; metallurgical test results; bulk density groundwater geotechnical and rock characteristics; potential deleterious or contaminating substances.</i>	Geological context and observations about the controls on mineralisation where these have been made are provided in the body of the report. 229 specific gravity measurements have been taken from the drill core recovered during the drilling program. These data are expected to be used to estimate bulk densities in future resource estimates. Eight Induced Polarisation (IP) lines have been completed in the northern area. Each line is approximately 1 kilometre in length lines are spaced 100m apart with a 50m dipole. The initial results indicate possible extension of the mineralisation with depth. Data will be interpreted including detailed re-processing and drill testing.

Criteria	JORC Code explanation	Commentary
		A ground magnetic survey and drone magnetic survey have been completed. The results of these data are being processed and interpreted with the geological information provided from surface and in the drilling and will be used to guide future exploration.
Further work	- <i>The nature and scale of planned further work (eg tests for lateral extensions or depth extensions or large-scale step-out drilling).</i> - <i>Diagrams clearly highlighting the areas of possible extensions including the main geological interpretations and future drilling areas provided this information is not commercially sensitive.</i>	• CEL Plans to undertake the following over the next 12 months • Additional data precision validation and drilling as required; • Detailed interpretation of known mineralized zones; • Geophysical tests for undercover areas. • Structural interpretation and alteration mapping using high resolution satellite data and geophysics to better target extensions of known mineralisation. • Field mapping program targeting extensions of known mineralisation. • Investigate further drilling requirements to upgrade both the unclassified mineralisation and mineralisation in the existing historical resources to meet JORC 2012 requirements; • Initial drill program comprising verification (twin holes) and targeting extensions of the historically defined mineralisation; • Further metallurgical test work on lower grade mineralisation in the intrusions and oxidised mineralisation.

Section 3 Estimation and Reporting of Mineral Resources

(Criteria listed in the preceding section also apply to this section.)

Criteria	JORC Code explanation	Commentary
Database integrity	- Measures taken to ensure that data has not been corrupted by for example transcription or keying errors between its initial collection and its use for Mineral Resource estimation purposes. - Data validation procedures used.	Geological logging completed by previous explorers was done on paper copies and transcribed into the drill hole database. The data was checked for errors. Checks can be made against the original logs and core photographs. Assay data is received in digital format. Backup copies are kept and the data is copied into the drill hole database. The drill hole data is backed up and is updated periodically by a Company GIS and data team.
Site visits	- Comment on any site visits undertaken by the Competent Person and the outcome of those visits. - If no site visits have been undertaken indicate why this is the case.	Site visits have been undertaken from 3 to 16 October 2019 15 to 30 November 2019 and 1-19 February 2020. The performance of the drilling program collection of data and sampling procedures were initiated during these visits.
Geological interpretation	- Confidence in (or conversely the uncertainty of) the geological interpretation of the mineral deposit. - Nature of the data used and of any assumptions made. - The effect if any of alternative interpretations on Mineral Resource estimation. - The use of geology in guiding and controlling Mineral Resource estimation. - The factors affecting continuity both of grade and geology.	The interpretation is considered appropriate given the stage of the project and the nature of activities that have been conducted. The interpretation captures the essential geometry of the mineralised structure and lithologies with drill data supporting the findings from the initial underground sampling activities. The most recent resource calculation (2006 and 2003 – La Mancha) used all core drilling at the time and detailed underground channel sampling collected by EPROM CMEC and La Mancha. Overlying assumptions included a reduction of the calculated grade in each resource block by a factor of 10% to account for possible errors in the analyses and samples. An arbitrary reduction factor was applied to the 2006 resource whereby the net reported tonnage was reduced by 25% for indicated resource blocks 50% for inferred resource blocks and 75% of potential mineral resource blocks. The reason for the application of these tonnage reduction factors was not outlined in the resource report. It is noted that at the time of this report La Mancha was in a legal dispute concerning the project with its joint venture partner and given the acquisition of a 200000 Oz per annum producing portfolio the project was likely no longer a core asset for La Mancha at that time. Additionally under the original acquisition agreement La Mancha had to issue additional acquisition shares based on resource targets. The effect of removing the assumptions relating to application of the arbitrary tonnage reduction factors applied increases the overall resource tonnage by in excess of 50%. Removing these correction factors would bring the overall tonnage and grade close the earlier (2003 1999 and 1996)

Criteria	JORC Code explanation	Commentary
		tonnage and grade estimates albeit in different categories (lower confidence) which are considered more appropriate. The mineralisation is defined to the skarn and vein bodies detailed cross section and plan maps were prepared for these bodies with their shapes used in controlling the resource estimate. The structure of the area is complex and a detailed structural interpretation is recommended as this may provide a better understanding of the continuity of mineralisation and possible extensions to it. The deposit contains bonanza gold values and while very limited twinning has indicated acceptable repeatability a rigorous study of grade continuity needs to be undertaken as part of future resource calculations.
Dimensions	- The extent and variability of the Mineral Resource expressed as length (along strike or otherwise) plan width and depth below surface to the upper and lower limits of the Mineral Resource.	For the historic resource no reliable information has been provided to the owner however through further ongoing investigation is being conducted by the owner to address this information gap.
Estimation and modelling techniques	- The nature and appropriateness of the estimation technique(s) applied and key assumptions including treatment of extreme grade values domaining interpolation parameters and maximum distance of extrapolation from data points. If a computer assisted estimation method was chosen include a description of computer software and parameters used. - The availability of check estimates previous estimates and/or mine production records and whether the Mineral Resource estimate takes appropriate account of such data. - The assumptions made regarding recovery of by-products. - Estimation of deleterious elements or other non-grade variables of economic significance (eg sulphur for acid mine drainage characterisation). - In the case of block model interpolation the block size in relation to the average sample spacing and the search employed. - Any assumptions behind modelling of selective mining units. - Any assumptions about correlation between variables. - Description of how the geological interpretation was used to control the resource estimates. - Discussion of basis for using or not using grade cutting or capping. - The process of validation the checking process used the comparison of model data to drill hole data and use of reconciliation data if available	The historic resource estimation techniques are considered appropriate. The 2003 and 2006 resources used a longitudinal section polygonal method was used for estimating resources with individual blocs representing weighted averages of sampled underground and/or areas of diamond drill pierce points with zones of influence halfway to adjacent holes. The area of the block was calculated in AutoCad directly from the longitudinal sections. Check assaying by PG Consulting returned values in the check assay sample which were 3.4% and 13% greater for Au and Ag than the original assays. A number pf previous resource estimates were available to check the 2006 resource estimate when the arbitrary tonnage reduction factors are removed brings the overall tonnage and grade close the earlier (2003 1999 and 1996) tonnage and grade estimates albeit indifferent categories which are considered more appropriate. It was assumed only gold silver and zinc would be recovered and that no other by products would be recovered. This is viewed as conservative given metallurgical data pointing to the production of a saleable zinc concentrate. Based on the preliminary metallurgy estimation of deleterious elements or other non-grade variables of economic significance was not required. The minimum mining width of 0.8m was assumed for veins less than 0.6m and for wider widths a dilution of 0.2m was used to calculate the grade.

Criteria	JORC Code explanation	Commentary
		No assumptions were made regarding correlation between variables. The mineralisation is defined within skarn and associated vein deposits. Detailed cross section and plan maps were prepared for these domains with their shapes used in controlling the resource estimate. Long sections of the veins and skarn were taken and sampling was plotted and the blocks outlined considering this. Grade cutting was not used in the calculation of the resource and no discussion was given as to why it was not employed. It is recommended that a study be undertaken to determine if an appropriate top cut need be applied No data is available on the process of validation.
Moisture	- Whether the tonnages are estimated on a dry basis or with natural moisture and the method of determination of the moisture content.	No data is available.
Cut-off parameters	- The basis of the adopted cut-off grade(s) or quality parameters applied.	The Mineral Resource Estimate is above a cut-off grade of 3.89 g/t Au. This is based on the assumed mining cost at the time of the estimate.
Mining factors or assumptions	- Assumptions made regarding possible mining methods minimum mining dimensions and internal (or if applicable external) mining dilution. It is always necessary as part of the process of determining reasonable prospects for eventual economic extraction to consider potential mining methods but the assumptions made regarding mining methods and parameters when estimating Mineral Resources may not always be rigorous. Where this is the case this should be reported with an explanation of the basis of the mining assumptions made.	The Mineral Resource Estimate considered the assumptions outlined below which are considered appropriate; - Metal prices: Au US\$550 Oz Ag US\$10 Oz - Metallurgical Recovery; Au – 80% Ag – 70% Zn - nil - Operating cost: US\$55t based on underground cut and fill mining and flotation and cyanidation combined The minimum mining width of 0.8m was assumed for veins less than 0.6m and for wider widths a dilution of 0.2m was used to calculate the grade.
Metallurgical factors or assumptions	- The basis for assumptions or predictions regarding metallurgical amenability. It is always necessary as part of the process of determining reasonable prospects for eventual economic extraction to consider potential metallurgical methods but the assumptions regarding metallurgical treatment processes and parameters made when reporting Mineral Resources may not always be rigorous. Where this is the case this should be reported with an explanation of the basis of the metallurgical assumptions made.	Historical metallurgical test-work assumptions were 80% recovery for Au, Ag and Zn. - The most recent historic test work was conducted in 1999 by Lakefield Research (cyanidation) and CIMM Labs (flotation) in Chile on 4 samples which all contain primary sulphide minerals and so can be considered primary, partial oxide or fracture oxide samples. - The test work was conducted using a 150 micron grind which would appear to coarse based on petrography conducted by CEL which shows that the gold particles average 30-40 microns. - Rougher flotation tests were performed with a 20 minute and 30 minute floatation time. Generally, the longer residence time improved recovery. Recoveries to concentrate for gold range from 59.6% - 80.6% and for silver from 63.1% – 87.2%.

Criteria	JORC Code explanation	Commentary
		- Knelson concentrate tests with floatation of tailings were also completed. Applying a joint process Knelson concentrator and floatation of the tailings of the concentrator it is found that the global recovery is approximately 80% for gold. - While the testwork was focused predominantly on gold recovery some rougher floatation testwork was undertaken targeting Zn recovery producing up to 85% recoveries. In sulphide samples this produced a Zn concentrate containing 42% Zn with grades in excess of 50% Zn in concentrate expected with additional floatation stages. - The report concluded that it was possible to produce a commercial Au-Ag concentrate and a Zn concentrate. - Extraction of gold and silver by cyanidation was tested on 3/8 and 3/4 inch (9.525mm and 19.05mm) crush sizes that are designed to test a heap leach processing scenario. Bottle roll of these crush size resulted in 41-39% gold recovery and 31-32% silver recovery with high cyanide consumption. No tests have been done on material at a finer grind size. More recently, CEL has completed initial metallurgical test work on a 147 kg composite sample of drill core from GMDD039, GMDD040, GMDD041, GNDD043, GNDD003 and GNDD018. The sample is of skarn mineralisation in limestone that has a weighted average grade of 10.4 g/t Au, 31.7 g/t Ag, 3.2 % Zn, 0.15 % Cu and 0.46 % Pb. Separate tests on 2 kg sub-samples were done with differing grinding times, Knelson and Mosley table gravity separation techniques and floatation techniques to provide a series of gravity and floatation concentrates. Key results are: - Combined gravity and floatation concentration process resulted in recoveries 85-94% for Au, 82-86% for silver and 77-80% for zinc. Cu had similar recoveries to Ag and Pb had similar recoveries to Zn. - A simple gravity separation followed by a sulfide floatation process when re-combined produced a single product with a median grade of 47 g/t Au, 120 g/t Ag and 13% Zn with a recovered weight of 24-33% of the sample weight. - Tailings fragment analysis indicates a grind of (p₈₀) 72-106 µm. Generally, a coarser grind resulted in a higher % weight recovered to the concentrate with a corresponding lower grade without significantly impacting recovery. - QEMSCAN analysis of the sample indicates much of the Zn not recovered is due to the presence of Zn oxide (franklinite) and silicates (hemimorphite). - Sulphides present are dominated by pyrite and sphalerite. Also present are chalcopyrite, pyrrhotite, chalcocite, bornite and galena.
Environmental factors or assumptions	- <i>Assumptions made regarding possible waste and process residue disposal options. It is always necessary as part of the process of determining reasonable prospects for eventual economic extraction to consider the potential environmental impacts of the mining and</i>	It is considered that there are no significant environmental factors which would prevent the eventual extraction of gold from the project. Environmental surveys and assessments will form a part of future pre-feasibility.

Criteria	JORC Code explanation	Commentary
	<i>processing operation. While at this stage the determination of potential environmental impacts particularly for a greenfields project may not always be well advanced the status of early consideration of these potential environmental impacts should be reported. Where these aspects have not been considered this should be reported with an explanation of the environmental assumptions made.</i>	
Bulk density	- Whether assumed or determined. If assumed the basis for the assumptions. If determined the method used whether wet or dry the frequency of the measurements the nature size and representativeness of the samples. - The bulk density for bulk material must have been measured by methods that adequately account for void spaces (vugs porosity etc) moisture and differences between rock and alteration zones within the deposit. - Discuss assumptions for bulk density estimates used in the evaluation process of the different materials.	Densities of 2.7 t/m3 were used for mineralised veins and 2.6 t/m3 for wall rock. No data of how densities were determined is available. The bulk densities used in the evaluation process are viewed as appropriate at this stage of the Project. CEL is collecting specific gravity measurements from drill core, which it is expected will be able to be used to estimate the block and bulk densities in future resource estimates. For RC drilling, the weights of material recovered from the drill hole is able to be used as a measure of the bulk density.
Classification	- The basis for the classification of the Mineral Resources into varying confidence categories. - Whether appropriate account has been taken of all relevant factors (ie relative confidence in tonnage/grade estimations reliability of input data confidence in continuity of geology and metal values quality quantity and distribution of the data). - Whether the result appropriately reflects the Competent Person's view of the deposit.	The Mineral Resource Estimate has both Indicated and Inferred Mineral Resource classifications under the National Instrument 43-101 code and is considered foreign. These classifications are considered appropriate given the confidence that can be gained from the existing data and results from drilling. The reliability of input data for the 2003 and 2006 resources is acceptable as is the confidence in continuity of geology and metal values quality quantity and distribution of the data. Appropriate account has been taken of all relevant factors with the exception of studies into the appropriateness of the application of a top cut. The reported 2006 NI43-101 (non-JORC Code compliant Measured and Indicated) estimate for the Hualilan Project is measured resource of 164294 tonnes averaging 12.6 grams per tonne gold and 52.1 g/t silver and 2.5% zinc plus an indicated resource of 51022 tonnes averaging 12.4 grams per tonne gold and 36.2 g/t silver and 2.6% zinc plus an inferred resource of 213952 tonnes grading 11.7 grams per tonne gold and 46.6 g/t silver and 2.3% zinc. (Source La Mancha resources Toronto Stock Exchange Release April 7 2007 - Interim Financials) – See Table 1. The 2006 estimate did not include the east-west mineralised Magnata Vein despite the known mineralisation in the Magnata Vein being drilled on a 25 x 50-metre spacing. The 2003 NI43-101

Criteria	JORC Code explanation	Commentary
		The earlier (1996 and 2000) Mineral Resource Estimates were audited and re-stated in a 2003 resource report. This independent report was done to NI-43-101 standard and the results of this report were released to the TSX. This report concluded that "Detailed resource calculations made by three different groups are seen to be realistic.
Discussion of relative accuracy/confidence	- Where appropriate a statement of the relative accuracy and confidence level in the Mineral Resource estimate using an approach or procedure deemed appropriate by the Competent Person. For example the application of statistical or geostatistical procedures to quantify the relative accuracy of the resource within stated confidence limits or if such an approach is not deemed appropriate a qualitative discussion of the factors that could affect the relative accuracy and confidence of the estimate. - The statement should specify whether it relates to global or local estimates and if local state the relevant tonnages which should be relevant to technical and economic evaluation. Documentation should include assumptions made and the procedures used. - These statements of relative accuracy and confidence of the estimate should be compared with production data where available.	There is sufficient confidence in the data quality drilling methods and analytical results that they can be relied upon. The available geology and assay data correlate well. The approach or procedure are deemed appropriate given the confidence limits. The main two factors which could affect relative accuracy is grade continuity and top cut. Grade continuity is variable in nature in this style of deposit and has not been demonstrated to date and closer spaced drilling is required to improve the understanding of the grade continuity in both strike and dip directions. It is noted that the results from the twinning of three holes by La Mancha are encouraging in terms of grade repeatability. The deposit contains very high grades and there is a potential need for the use of a top cut. It is noted that an arbitrary grade reduction factor of 10% has already been applied to the resource as reported. No production data is available for comparison
