

Koppies Uranium Project Drilling Update

Highlights:

- Confirmation of mineralisation extension between Koppies 2 and Koppies 3 across a broad area
- Large areas of continuous mineralisation south of Koppies 2 resource
- Koppies 2 has the potential to extend southeast and east
- Mineralisation confirmed below the base of shallow holes at Koppies 1 and 2, confirming the potential for resource growth within the existing resource shell
- Two drill rigs working on resource definition at Koppies 3

Elevate Uranium Limited ("Elevate Uranium", or the "Company") (ASX:EL8) (OTCQX:ELVUF) is pleased to provide an update on its drilling programs at the Koppies Uranium Project in Namibia.

Downhole gamma probe data has been received for an additional 340 holes drilled around Koppies 1 and 2 and at Koppies 3 since the ASX announcement titled "2023 Drilling Program Underway" dated 30 January 2023.

The latest drilling results have highlighted the following.

- Drilling north of Koppies 2 confirms a continuous connection between Koppies 2 and 3 across a broad area.
- Large areas of continuous mineralisation confirmed south of Koppies 2, through to the southern boundary of the Koppies tenement, connecting with Koppies 4.
- Mineralisation intersected in holes to the southeast and east of Koppies 2, indicating potential for extensions.
- Some previously drilled holes within the resource shells at Koppies 1 and 2 were twinned and drilled deeper than the original resource holes. The twinned holes intersected mineralisation beneath the base of the original holes, indicating that there is potential for additional mineralisation from future, deeper drill programs (holes up to about 25 metres deep). This indicates that additional deeper, twin drilling of a significant number of the original resource holes will be required.
- Mineralisation intersected in drill holes between Koppies 1 and 2 indicates the potential for Koppies 1 and 2 to connect.

Elevate Uranium's Managing Director, Murray Hill, commented:

"The latest drill results confirm the connection between Koppies 1, 2, 3 and 4, and also confirm our proposition that there are additional areas likely to contain mineralisation, within the resource shell boundaries, and they also indicate the potential for the resource at Koppies 2 to grow to the east. With

most of the Koppies tenement now indicating broadly spaced mineralisation, we have numerous areas for additional drilling programs. Currently, we have decided to focus our attention on Koppies 3, with one drill rig moving north from Koppies 2 drilling at a spacing of 200 metres by 200 metres to confirm the outline of the mineralised envelope. A second drill rig will follow drilling in a 100 metre by 100 metre hole pattern, to enable estimation of a JORC resource."

Notable intersections from this drilling campaign include:

- ♦ KOR1250 5.5 m at 1,121 ppm eU₃O₈ from 9.5 m
- KOR1159 2 m at 390 ppm eU₃O₈ from 13 m
- ♦ KOR1439 4 m at 336 ppm eU₃O₈ from 5.5 m
- ✤ KOR1177 3 m at 331 ppm eU₃O₈ from 21 m
- ♦ KOR1289 6 m at 265 ppm eU₃O₈ from 12 m
- ♦ KOR1440 8.5 m at 252 ppm eU₃O₈ from surface
- ✤ KOR1253 17.5 m at 240 ppm eU₃O₈ from 4.5 m
- ♦ KOR1584 4.5 m at 223 ppm eU₃O₈ from 6 m
- ♦ KOR1251 21 m at 212 ppm eU₃O₈ from 1 m
- ✤ KOR1228 8 m at 200 ppm eU₃O₈ from 14 m

The Company has previously indicated potential for additional mineralisation around and below the palaeochannels of the Koppies 1 and 2 resources. A number of holes were drilled in this program adjacent to holes previously drilled between 2 and 4 metres deep, to test for mineralisation beneath the base of the holes. These holes, called twin holes, intersected mineralisation at Koppies 1 and Koppies 2 beneath the base of the original holes, confirming the Company's proposition and highlighting potential for an increase to the resource as further drilling is undertaken within the resource area boundaries.

However, the medium-term focus of the drill programs has moved to Koppies 3, where the two drill rigs are now working. The first rig is drilling out the identified mineralised envelope to a 200 metre by 200 metre spacing to enable clearer definition of the mineralised outline, but also testing extensions to mineralisation outside of the defined envelope in areas where the geological team consider that there is potential for extensions. The second rig is undertaking a detailed resource definition drill program within the mineralised envelope at a drill spacing of 100 metres by 100 metres to facilitate estimation of a JORC resource.

After completion of resource drilling at Koppies 3, the rigs will return to the Koppies 1, 2 and 4 areas to further define the mineralised envelope and complete resource drilling.

Figure 1 locates the drill holes from the drilling programs completed to date, which are outside of the Koppies 1 and Koppies 2 defined mineral resource areas. A total of 866 holes for 20,924 metres have been drilled outside of the Koppies resource and shown in Figure 1. This announcement includes 340 holes for 8,163 metres drilled since the announcement of 30 January 2023.

The proximity of Koppies to the Company's other tenements in the Namib area is shown in Figure 3, with the proximity of Koppies to the Company's other Namibian tenements in Figure 4.

JORC (2012) Inferred Mineral Resource Estimate at 100 ppm Cut-off Grade

Koppies Uranium Resource:

The Company confirms that the Mineral Resource Estimates for the Koppies 1 and Koppies 2 deposits have not changed since the annual review as disclosed in the 2022 Annual Report. The Company is not aware of any new information, or data, that effects the information in the 2022 Annual Report and confirms that all material assumptions and technical parameters underpinning the estimates continue to apply and have not materially changed.

Competent Persons Statement – General Exploration Sign-Off

The information in this announcement as it relates to exploration results, interpretations and conclusions was provided by Ms Asha Rao, who is a Member of both the AusIMM and the Australasian Institute of Geoscientists (AIG). Ms Rao has sufficient experience that is relevant to the style of mineralisation and type of deposit under consideration, and to the activity being undertaken to qualify as a Competent Person, as defined in the JORC 2012 edition of the "Australasian Code for Reporting of Mineral Resources and Ore Reserves". Ms Rao consents to the inclusion of this information in the form and context in which it appears.

Table 1 details intervals greater than 100 ppm eU_3O_8 with a minimum 0.5 metre thickness and Table 2 details collars for holes drilled around Koppies 1 and 2 and at Koppies 3 since the ASX announcement titled "2023 Drilling Program Underway" dated 30 January 2023.

JORC Code, 2012 Edition – Table 1

Section 1 Sampling Techniques and Data

(Criteria in this section apply to all succeeding sections.)

Criteria	JORC Code explanation	Commentary
Sampling techniques	 Nature and quality of sampling (e.g. cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling. 	 Uranium grade was estimated using downhole gamma probes. Wet chemical analysis will be used to check, and validate, selected downhole gamma intervals during subsequent drilling programs.
	 Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used. 	• Gamma probes provide an estimate of uranium grade in a volume extending approximately 40cm into the surrounding rock from the probe inside the drillhole. Gamma data are therefore much more representative of <i>in situ</i> mineralisation than wet chemical samples which represent a much smaller fraction of this volume. The gamma probes utilised for the Koppies drilling have been calibrated at the Pelindaba facility in South Africa and at the Husab mine in Namibia.
	• Aspects of the determination of mineralisation that are Material to the Public Report.	• Gamma data (as counts per second) from calibrated probes are converted into equivalent uranium values (eU ₃ O ₈) using appropriate calibration and casing factors. Gamma probes can overestimate uranium grade if high thorium values are present or if disequilibrium exists between uranium and its daughters. Neither is thought to be an issue here, although samples will be submitted for analysis of disequilibrium, as a check.
	 In cases where 'industry standard' work has been done this would be relatively simple (e.g., 'reverse circulation drilling was used to obtain 1 m samples from which 3 kg was pulverised to produce a 30 g charge for fire assay'). In other cases, more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (e.g., submarine nodules) may warrant disclosure of detailed information. 	• The method of drilling is reverse circulation, during which samples are obtained from every metre and split at the drill rig into smaller 2.5 kg samples. These samples are then stored and, following subsequent analysis of the downhole gamma data, are selectively chosen for wet chemical analysis as described earlier in this section.
Drilling techniques	 Drill type (e.g. core, reverse circulation, open-hole hammer, rotary air blast, auger, Bangka, sonic, etc) and details (e.g. core diameter, triple 	 Reverse circulation (RC) is the main drilling technique used. Hole diameter is approximately 140 mm. Holes are relatively shallow

Criteria	JORC Code explanation	Commentary
	or standard tube, depth of diamond tails, face-sampling bit or other type, whether core is oriented and if so, by what method, etc).	(generally 25 to 30 m) and vertical, therefore downhole dip and azimuth were not recorded other than at the collar.
Drill sample recovery	 Method of recording and assessing core and chip sample recoveries and results assessed. 	• Bags containing 1 m of chip samples were weighed at the rig and weights recorded. The nominal weight of a 1 m sample is 25 kg and recovery is assessed using the ratio of actual to ideal sample weight.
	 Measures taken to maximise sample recovery and ensure representative nature of the samples. 	• Standard operating procedures are in place at the drill rig in order to ensure that sampling of the drilling chips is representative of the material being drilled.
	 Whether a relationship exists between sample recovery and grade and whether sample bias may have occurred due to preferential loss/gain of fine/coarse material. 	 Uranium grade is derived from gamma measurement and sample bias is not an issue. There is a possibility that some very fine uranium is lost during drilling, and this will be investigated by twinning some RC holes with diamond holes in a later campaign.
Logging	 Whether core and chip samples have been geologically and geotechnically logged to a level of detail to support appropriate Mineral Resource estimation, mining studies and metallurgical studies. 	 Chip samples are visually logged to a basic level of detail. Parameters recorded include lithology, colour, sample condition (i.e., wet or dry) and total gamma count using a handheld scintillometer. This level of detail is suitable for a mineral resource estimate which will differentiate between palaeochannel and basement-hosted mineralisation.
	 Whether logging is qualitative or quantitative in nature. Core (or costean, channel, etc) photography. 	• Logging is qualitative. Reference photographs are taken of RC chips in chip trays.
	 The total length and percentage of the relevant intersections logged. 	All samples were logged.
Sub- sampling	 If core, whether cut or sawn and whether quarter, half or all core taken. 	Core holes have not yet been drilled at Koppies 3.
techniques and sample preparation	 If non-core, whether riffled, tube sampled, rotary split, etc and whether sampled wet or dry. 	 1 m RC chips were subsampled to approximately 2.5 kg using a 3- way riffle splitter mounted on the RC rig. A second 2.5 kg sample was collected as a field duplicate and reference sample. The vast majority of the samples were dry.
	 For all sample types, the nature, quality and appropriateness of the sample preparation technique. 	 Pre-selected samples chosen for geochemical analysis are shipped to Intertek Genalysis preparation laboratory at Tschudi for crushing and grinding.
	 Quality control procedures adopted for all sub-sampling stages to maximise representivity of samples. 	 Certified reference material, duplicate samples and blank samples are submitted at a rate of 1 per 20.
	• Measures taken to ensure that the sampling is representative of the in situ material collected, including for instance results for field duplicate/second-half sampling.	• Comparison of analyses of 2.5 kg field duplicate samples to date suggests that the mineralisation is somewhat nuggetty, however this is overcome by the use of gamma logging which measures a significantly larger volume.
	Whether sample sizes are appropriate to the grain size of the material being sampled.	 This has not been investigated however the methodology used is similar to analogous deposits at Tumas and Langer Heinrich.

Criteria	JORC Code explanation	Commentary
Quality of assay data and laboratory tests	 The nature, quality and appropriateness of the assaying and laboratory procedures used and whether the technique is considered partial or total. 	• Samples will be analysed at Genalysis state of the art facility in Perth, Australia, using a sodium peroxide fusion and ICP-MS finish which measures total uranium content of the samples. This method produces precise and accurate data and has no known issues with respect to uranium analysis.
	• For geophysical tools, spectrometers, handheld XRF instruments, etc, the parameters used in determining the analysis including instrument make and model, reading times, calibration factors applied and their derivation, etc.	• The gamma probes used will be checked against assays by logging drill holes for which the Company has geochemical assays. The correlation between assays and derived equivalent uranium values is currently unknown for the prospect however it is currently assumed that it will be similar to the adjacent Koppies 1 and 2 deposits.
	 Nature of quality control procedures adopted (eg standards, blanks, duplicates, external laboratory checks) and whether acceptable levels of accuracy (ie lack of bias) and precision have been established. 	 Review of the company's QA/QC sampling and analysis confirms that the analytical program has previously provided data with good analytical precision and accuracy. No external laboratory (i.e. umpire) checks have been undertaken.
Verification of sampling	The verification of significant intersections by either independent or alternative company personnel	 Not yet verified by comparison of downhole gamma and wet chemica grades. No external verification has been undertaken to date
and assaying	The use of twinned holes.	 Twin holes were drilled adjacent to shallow holes (2 to 4 m deep) to test for mineralisation beneath the base of the original hole.
	 Documentation of primary data, data entry procedures, data verification, data storage (physical and electronic) protocols. 	 Downhole gamma data are provided as LAS files by the company's geophysical logging contractor which are imported into the company's hosted Datashed 5 database where eU₃O₈ is calculated automatically. Data are stored on a secure server maintained by the database consultants, with data made available online.
	Discuss any adjustment to assay data.	 No adjustment undertaken than those based on standard downhole gamma logging practices.
Location of data points	 Accuracy and quality of surveys used to locate drill holes (collar and down-hole surveys), trenches, mine workings and other locations used in Mineral Resource estimation. 	• Due to the nature of the drilling, most collar locations were fixed using a handheld GPS unit. No downhole surveys were undertaken.
	• Specification of the grid system used.	• The grid system is Universal Transverse Mercator, zone 33S (WGS 84 datum).
	Quality and adequacy of topographic control.	• Topographic control is provided by a digital elevation model derived from airborne geophysical surveys which provides adequate resolution for this level of investigation.
Data spacing and distribution	Data spacing for reporting of Exploration Results.	• The early stages of this program were exploratory in nature and used a variety of drill spacings. The drill line spacing varied from 200m-500m x 100m-200m along the drill lines.
	• Whether the data spacing and distribution is sufficient to establish the	This spacing is believed sufficient to demonstrate continuity of

Spacing of the current drilling program are 200 x 200m for the mineralisation definition stage, and 100 x 100m for the JORC resource infill drilling phase.
	Whether sample compositing has been applied.	 Gamma measurements are taken every 10 cm downhole. 10 cm measurements are composited to 1 m intervals.
entation lata in htion to blogical ucture	 Whether the orientation of sampling achieves unbiased sampling of possible structures and the extent to which this is known, considering the deposit type. If the relationship between the drilling orientation and the orientation of key mineralised structures is considered to have introduced a sampling bias, this should be assessed and reported if material. 	 Uranium mineralisation is distributed in moderately continuous horizontal layers. All holes are drilled vertically and therefore intercepts represent the true thickness.
nple urity	• The measures taken to ensure sample security.	Samples at the drill rig are placed into plastic bags and transported from the drill site to a contract transport company in Swakopmund for transfer to the Genalysis sample preparation facility in Tschudi. A second split (field duplicate) is placed into plastic bags and transported to Elevate's storage shed in Swakopmund by company personnel where it is kept under lock and key. Upon completion of the preparation work the remainder of the drill chip sample bags for each hole are packed into drums and then stored in Elevate's dedicated sample storage shed in Swakopmund. Upon completion of the assay work the remainder of the drill chip sample bags for each hole will be packed back into drums and then stored in Elevate's dedicated sample storage shed in Swakopmund.
dits or iews	• The results of any audits or reviews of sampling techniques and data.	No audits have been undertaken.

Exploration Results

ection also apply to this section.)

Criteria	JORC Code explanation	Commentary
<i>Mineral tenement and land tenure status</i>	 Type, reference name/number, location and ownership including agreements or material issues with third parties such as joint ventures, partnerships, overriding royalties, native title interests, historical sites, wilderness or national park and environmental settings. 	• The Exploration Results relate to exclusive prospecting licence EPL 6987 "Koppies" and EPL 7279 "Ganab West", both owned 100% by Marenica Ventures Pty Ltd, a 100%-owned subsidiary company of Elevate Uranium Ltd. EPL 6987 was granted on 10 April 2019 and EPL 7279 16 May 2019. The EPL is located within the Namib

Naukluft National Park in Namibia. There are no known impediments

Criteria	JORC Code explanation
	 The security of the tenure held at the time of reporting along with any known impediments to obtaining a licence to operate in the area.
Exploration done by other parties	Acknowledgment and appraisal of exploration by other parties.
Geology	• Deposit type, geological setting and style of mineralisation.
Drill hole Information	 A summary of all information material to the understanding of the exploration results including a tabulation of the following information for all Material drill holes: easting and northing of the drill hole collar elevation or RL (Reduced Level – elevation above sea level in metres) of the drill hole collar dip and azimuth of the hole down hole length and interception depth hole length. If the exclusion of this information is justified on the basis that the information is not Material and this exclusion does not detract from the understanding of the report, the Competent Person should clearly explain why this is the case.
Data aggregation methods	 In reporting Exploration Results, weighting averaging techniques, maximum and/or minimum grade truncations (e.g. cutting of high grades) and cut-off grades are usually Material and should be stated. Where aggregate intercepts incorporate short lengths of high grade results and longer lengths of low grade results, the procedure used for such aggregation should be stated and some typical examples of such aggregations should be shown in detail. The assumptions used for any reporting of metal equivalent values

he time of reporting along with any licence to operate in the area.	 EPL 6987 was renewed on 10 April 2022 for a period of two years. EPL 7279 was renewed on 10 June 2022 for a period of two years.
exploration by other parties.	• General Mining is known to have previously explored the area covered by the tenement in the late 1970's. No drilling is recorded.
d style of mineralisation.	 Uranium mineralisation occurs as secondary carnotite enrichment in calcretised palaeochannel and sheet wash sediments and adjacent weathered bedrock. Uranium mineralisation is generally surficial, strata bound and hosted by Cenozoic and possibly Tertiary sediments, which include from top to bottom scree sand, gypcrete, calcareous sand and calcrete. The majority of the mineralisation is hosted in calcrete. Underlying weathered Proterozoic bedrock is occasionally also mineralised, as calcite veins.
rial to the understanding of the Ilation of the following information hole collar I – elevation above sea level in	 340 holes for a total of 8,163 m have been drilled. All holes were drilled vertically and intersections measured present true thicknesses. Table 2 lists all the drill hole locations.
ion depth

eighting averaging techniques, runcations (e.g. cutting of high vally Material and should be stated.	Reported grades have not been cut.
orate short lengths of high grade rade results, the procedure used	• All grade intervals are arithmetic averages over the stated interval at a cut-off of 100 ppm eU ₃ O ₈ . Up to 0.5 m of waste is allowed in each

Commentary

to the project.

Not relevant.

interval.

Criteria	JORC Code explanation	Commentary
	should be clearly stated.	
Relationship between mineralisatio	• These relationships are particularly important in the reporting of Exploration Results.	• The mineralisation is sub-horizontal and the majority of the drilling was vertical, therefore, mineralised intercepts are considered to represent true widths.
n widths and intercept lengths	 If the geometry of the mineralisation with respect to the drill hole angle is known, its nature should be reported. 	
iongtile	 If it is not known and only the down hole lengths are reported, there should be a clear statement to this effect (e.g. 'down hole length, true width not known'). 	• Not relevant.
Diagrams	 Appropriate maps and sections (with scales) and tabulations of intercepts should be included for any significant discovery being reported These should include, but not be limited to a plan view of drill hole collar locations and appropriate sectional views. 	 Maps and sections are included in the text.
Balanced reporting	 Where comprehensive reporting of all Exploration Results is not practicable, representative reporting of both low and high grades and/or widths should be practiced to avoid misleading reporting of Exploration Results. 	 Comprehensive reporting of all Exploration Results from this drilling program are detailed in this announcement.
Other substantive exploration data	 Other exploration data, if meaningful and material, should be reported including (but not limited to): geological observations; geophysical survey results; geochemical survey results; bulk samples – size and method of treatment; metallurgical test results; bulk density, groundwater, geotechnical and rock characteristics; potential deleterious or contaminating substances. 	 Extensive drilling has been completed by the Company on EPL 6987 over the past four years.
Further work	 The nature and scale of planned further work (e.g. tests for lateral extensions or depth extensions or large-scale step-out drilling). Diagrams clearly highlighting the areas of possible extensions, including the main geological interpretations and future drilling areas, provided this information is not commercially sensitive. 	 A resource drilling program is expected to be completed at Koppies 3. See text.
