

## Vital's optimized MRE delivers 56% increase in Measured + Indicated resources for Tardiff rare earth deposit

### Highlights:

- New Tardiff MRE total resource tonnage (across all categories) of 192.7 million tonnes at 1.3% total rare earth oxide (TREO), containing 2.5Mt TREO.
- Tardiff is estimated to contain 636,000 tonnes of NdPr (neodymium oxide + praseodymium oxide).
- Incorporating all the latest drilling data this new estimate, compared to the April 2024 MRE, delivers:
  - 70% increase in reported tonnes in the Indicated Resource category;
  - 56% increase in reported tonnes in Measured + Indicated Resource categories;
  - 2% increase in contained NdPr;
  - Niobium (Nb<sub>2</sub>O<sub>5</sub>), hosted within the same geological formations hosting the rare earth mineralisation, reported for the first time.
- Current MRE is reported above a 0.7% TREO cutoff grade instead of a metal equivalent value previously used.
- Vital is using the updated Tardiff MRE as the basis for a Scoping Study to examine the size and scalability of future production scenarios. This is expected in the coming weeks.

Vital Metals Limited (ASX: VML) ("Vital", "Vital Metals" or "the Company") is pleased to report an updated Mineral Resource estimate ("MRE") for the Tardiff Upper Zone ("Tardiff"), part of the Nechalacho Rare Earths Project (the "Project"), located in Northwest Territories (NWT), Canada.

The current MRE follows Vital's completion of resource definition drilling program at Tardiff in 2023, totalling 74 holes for 6,664m, which returned high-grade results up to 8% TREO.

The current MRE features a total resource tonnage (across all categories) of 192.7Mt grading 1.3% TREO and 0.3% Nb<sub>2</sub>O<sub>5</sub>, containing 2.52Mt TREO including 636,000t of NdPr.

**Vital Managing Director and CEO Lisa Riley said:** "Our updated MRE for the Tardiff deposit shows increased confidence in the deposit, with a 70% increase in the Indicated Resource tonnages and a 56% increase in the Measured + Indicated Resource tonnages compared to our April 2024 historical MRE, while our Inferred Resource tonnages have decreased by more than 20%. While our overall totals of contained TREO and NdPr have only slightly increased on the April 2024 historical MRE, based on the drilling we completed in 2023, we now have

more confidence that this is a truer representation of what this deposit holds.

*“The current MRE is the final piece awaited for inclusion in our Tardiff Scoping Study, which is now due for delivery in the coming weeks.”*

Vital VP Exploration Natalie Pietrzak-Renaud: *“The positive changes to the current MRE compared to the April 2024 historical MRE is largely based on the inclusion of the 2023 drill results, the 2024 metallurgical test results we obtained from our 2023 collected composite Tardiff sample, and the carefully considered metrics we used as inputs. Our approach is to establish outputs that are realistic pathways for project development. With the work we completed on the MRE and the forthcoming Scoping Study, we have, and continue, to build a solid foundation of data and knowledge to advance our project.”*

The Tardiff MRE is reported within an optimized open-pit shell using Studio NPVS from the Datamine Suite. The optimized pit shell was generated using a 45° maximum final pit wall, and a 150m RL lower pit limit.

Tardiff contains rare earth element (“**REE**”) and Niobium mineralisation hosted within a nepheline syenite intrusion. Recent metallurgical test work indicates strong potential to produce neodymium oxide (Nd<sub>2</sub>O<sub>3</sub>) and praseodymium oxide (Pr<sub>6</sub>O<sub>11</sub>), which are light rare earth oxides (LREO) with magnetic properties and are in demand due to their use in technologies such as high-strength magnets, aircraft engines, and various industrial and electronic applications. The recent metallurgical test work also indicates an opportunity to further investigate and advance the potential opportunity to recover niobium minerals from Tardiff ore. Niobium is in demand due to its low oxidation point and relatively high melting point. It is used as an alloy in aeronautic engines, electronic applications (due to its superconducting properties) and as an additive to lithium-ion batteries to enhance battery life.

The current MRE represents a significant increase in reported tonnes in the Indicated Mineral Resource category in comparison to the historical MRE completed in April 2024 and a decrease in reported tonnes in the Inferred Mineral Resource category. The current MRE is also reported above a 0.7% TREO cutoff grade instead of a metal equivalent value as previously used.

The MRE is presented in Table 1 and is reported above a cutoff grade of 0.7% total rare earth oxides (TREO). The Mineral Resource estimate includes reporting of Nd<sub>2</sub>O<sub>3</sub> and Pr<sub>6</sub>O<sub>11</sub>, NdPr (Nd<sub>2</sub>O<sub>3</sub> plus Pr<sub>6</sub>O<sub>11</sub>) and Nb<sub>2</sub>O<sub>5</sub>.

**Table 1. Tardiff Mineral Resource Estimate, TREO ≥ 0.7%**

| JORC Resource Classification | Tonnage      | Average Grade (%) |                                |                                 |                                | Contained Oxide |            |
|------------------------------|--------------|-------------------|--------------------------------|---------------------------------|--------------------------------|-----------------|------------|
|                              |              | TREO              | Nd <sub>2</sub> O <sub>3</sub> | Pr <sub>6</sub> O <sub>11</sub> | Nb <sub>2</sub> O <sub>5</sub> | TREO Kt         | NdPr Kt    |
| Measured                     | 7.6          | 1.48              | 0.28                           | 0.08                            | 0.24                           | 112             | 27         |
| Indicated                    | 41.0         | 1.29              | 0.25                           | 0.07                            | 0.25                           | 528             | 131        |
| Measured + Indicated         | 48.6         | 1.32              | 0.26                           | 0.07                            | 0.25                           | 640             | 158        |
| Inferred                     | 144.1        | 1.31              | 0.26                           | 0.07                            | 0.32                           | 1,883           | 477        |
| <b>Total</b>                 | <b>192.7</b> | <b>1.31</b>       | <b>0.26</b>                    | <b>0.07</b>                     | <b>0.30</b>                    | <b>2,523</b>    | <b>636</b> |

Notes:

1. Due to effects of rounding, the total may not represent the sum of all components.
2. TREO (ppm) includes: Light Rare Earth Oxides (LREO):  $\text{La}_2\text{O}_3$ ,  $\text{CeO}_2$ ,  $\text{Pr}_6\text{O}_{11}$ ,  $\text{Nd}_2\text{O}_3$ ,  $\text{Sm}_2\text{O}_3$ ; and Heavy Rare Earth Oxides (HREO):  $\text{Tb}_4\text{O}_7$ ,  $\text{Dy}_2\text{O}_3$ ,  $\text{Ho}_2\text{O}_3$ ,  $\text{Er}_2\text{O}_3$ ,  $\text{Tm}_2\text{O}_3$ ,  $\text{Yb}_2\text{O}_3$ ,  $\text{Lu}_2\text{O}_3$ ,  $\text{Eu}_2\text{O}_3$ ,  $\text{Gd}_2\text{O}_3$ ; +  $\text{Y}_2\text{O}_3$
3. Mineral Resource is reported from blocks at or above the 150 m RL and within unconstrained optimised open pit shell "Optimized\_Pits\_2\_Pit\_85\_100tr/pt"
4. Revenue in cutoff grade calculation is attributable to  $\text{Nd}_2\text{O}_3$  and  $\text{Pr}_6\text{O}_{11}$
5.  $\text{NdPr} = \text{Nd}_2\text{O}_3 + \text{Pr}_6\text{O}_{11}$
6. Mineral Resources that are not Mineral Reserves do not have demonstrated economic viability.
7. The Mineral Resource effective date is 18<sup>th</sup> December.

The MRE features a total resource tonnage (across all categories) of 192.7 Mt grading 1.3% TREO and 0.3%  $\text{Nb}_2\text{O}_5$  containing 2,523 Kt TREO including 636 Kt of NdPr. The MRE is reported within an optimized open pit shell using Studio NPVS from the Datamine Suite. The optimized pit shell was generated using a 45 degree maximum final pit wall, and a 150 m RL lower pit limit. The optimized pit shell is presented in Figure 1 as the unconstrained pit.

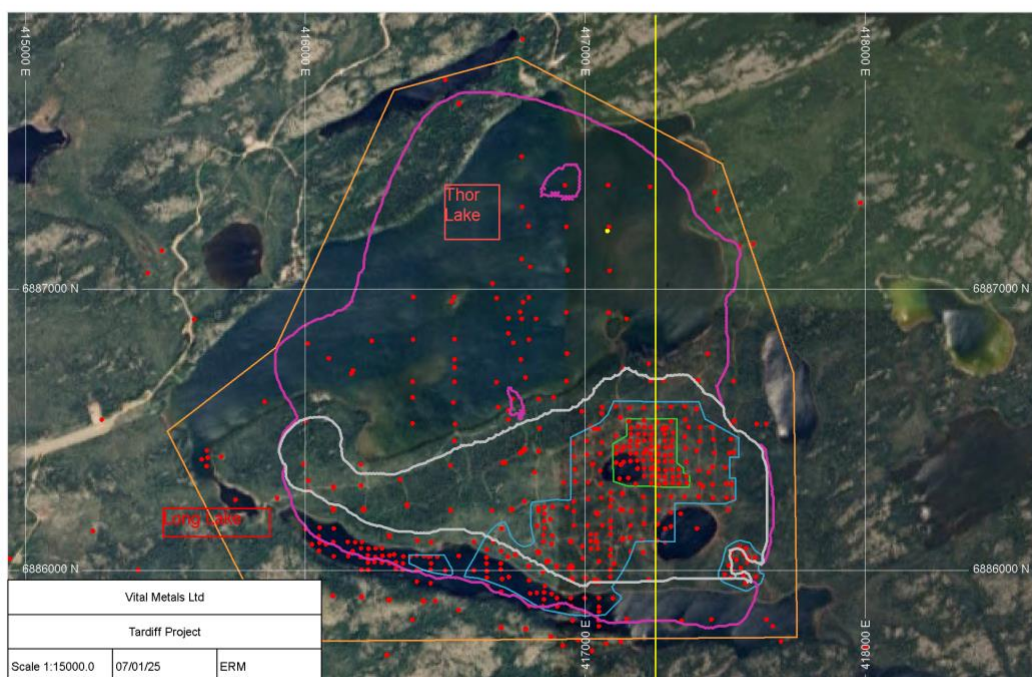

The Competent Persons (CPs) are of the opinion that the Tardiff deposit is of sufficient grade, quantity, and coherence to meet the criteria for reasonable prospects for eventual economic extraction (RPEEE). The Tardiff deposit is located 100 km southwest of Yellowknife, NWT via helicopter and is also readily accessible by boat and then a short distance by road to the Project area. Mineralisation outcrops in places, and otherwise covered by up to 20 m of overburden (tillite) and / or unmineralized, or low grade syenite. Canada is a mature mining jurisdiction and supports the development of renewable energy and critical minerals, subject to the required environmental and social license approvals. The MRE is reported within an optimised open-pit shell with appropriate costs and mining parameters applied to the optimisation process.

The Project is at an early stage of appraisal and studies are required to assess environment and social governance (ESG) issues. Some Indicated and Measured Mineral Resources are located below two small lakes, and Vital has advised the CP that these lakes are very shallow, freeze completely in winter, and host no fish. The Competent Person therefore considers there to be RPEEE for reporting Mineral Resources below these two small lakes. A significant proportion of the Inferred Mineral Resource is located beneath Thor and Long Lakes (refer to Figure 1). These lakes are relatively shallow (<5 m in depth) but contain significant volumes of water. The RPEEE considered (at a high level) whether it would be feasible to dewater the lakes to allow open-pit mining, and what the ESG considerations would be if the lakes were drained. Dewatering of the larger lakes may be possible, with appropriate pumps and drainage options, such as into Great Slave Lake, however detailed studies by appropriate technical experts are required. Other avenues of development are possible including underground extraction and should be investigated.

Vital recognizes that ongoing and in-depth discussions are required to identify and address specific concerns, limitation parameters and conditions for resource development, including the potential for extraction under the lake, which will be incorporated into the project development. Preliminary discussions with local communities suggest that the Thor and Long lakes do not hold specific historical or cultural significance. There is anecdotal evidence that suggests the lakes are host to species that are not on the endangered species lists. Discussions are underway and will continue to evolve during the advancement of the project.

The Competent Person is of the opinion that Vital needs to carry out considerable work to understand the ecology of the lakes, and to gain a firm understanding of the local communities'

consideration of the lakes, which should be carried out in the near term. Work will include evaluation of the alternative potential for underground extraction. This work will support current and future mining studies. Until then, the Competent Person is of the opinion that RPEEE considerations are met to report a MRE beneath the lakes.

**Figure 1:** Drill hole collar plot – Tardiff drilling 2023

**Notes for Figure 1:** Drill hole collars (red), Mineral Resource (constrained) optimized pit shell outline (grey), unconstrained optimal pit shell (magenta) as used for reporting of Mineral Resource, Measured resource classification polygon (green), Indicated polygon (cyan), Inferred polygon (orange). Satellite image of project presented as an underlay, showing Thor and Long Lakes, and two small lakes within the Measured and Indicated footprint. Yellow line is Easting 417250 as referenced in Figures 2 and 3.

## Geology and Geological Interpretation

The Tardiff deposit is hosted near the top of a layered nepheline syenite intrusion, which is part of an anorogenic alkaline intrusive complex, the Paleoproterozoic Blatchford Lake Igneous Complex. The Tardiff deposit consists of a series of rocks with increasing peralkaline characteristics at depth. It is virtually undeformed, and the rock units and mineralisation are generally sub-horizontal and can be traced for hundreds of metres. The REE mineralisation is hosted in hydrothermally altered syenite collectively referred to as the Upper and Basal Zones and the REE are mainly contained in the minerals bastnäsite-(Ce), synchysite-(Ce), parasite-(Ce), fergusonite-(Y), samarskite-(Y), allanite-(Ce), and monazite-(Ce). Niobium mineralisation is dominantly contained in ferrocolumbite and fergusonite-(Y).

REO mineralisation at Tardiff is layered in separate zones of light rare earths at the top of the deposit (Upper Zone) and a mixture of light and heavy REO mineralisation in the lower part of the deposit (Basal Zone). The current Tardiff MRE reported here is hosted within the upper

zone and is dominated by LREO mineralisation. There are some trends in chemical and mineralogical characteristics in the Nechalacho deposit that have both geological and metallurgical significance. These trends are most apparent in vertical zoning of the deposit with respect to the proportion of heavy rare earth elements (HREE) and light rare earth elements (LREE). In general, the HREE relative to the LREE show a distinct vertical zonation with increasing HREE to depth.

The continuity of REE-mineralization is associated with hydrothermal alteration and mineralogical variations in precursor lithological units. Alteration assemblages of secondary potassium feldspar replacement of early syenite, the destruction of pre-existing mafic minerals and/or the pervasive replacement by magnetite+/-chlorite+/- biotite+/- zircon alteration assemblages are strong visual indicators for higher grade REE-mineralization. The Nb mineralisation broadly follows similar trends of REE mineralisation and variations in grade.

A nominal 0.7% TREO value combined with lithological logging information was used for developing mineralogical wireframes in Leapfrog Geo software (mineralisation models 1, 2, 3, and 4). The cut-off grade was previously used to support the historical estimate (published 4<sup>th</sup> April 2024) and is supported by analysis of a log-probability plot of sample assays for TREO. Approximately 50% of the TREO assays have grades  $\geq 0.7\%$  TREO. The Leapfrog model used to create the models supporting the previous MRE were updated using drill hole sample analyses from the 2023 drilling, thereby maintaining a consistent approach to the geological interpretation.

Unmineralized country rock lithology, as well as overburden, diabase, and unmineralized syenite were constrained by wireframes.

## Drilling Techniques

Diamond core drilling using PQ, NQ, and HQ diameter core tubes with wireline recovery was used for all the drilling at Tardiff. A limited number of oriented core holes were drilled by Avalon for geotechnical purposes. Frozen lake surfaces allow for drilling through the lakes in winter months.

HQ diameter diamond drilling was used for the 2023 drill program by Vital. As the holes were short and vertical no orientations of the 2023 drill cores were undertaken.

A total of 484 drill holes (26,971 m) intersect the mineralisation domains, including 73 holes (4,741 m) drilled by Vital in 2023. Drill spacing is typically 25 m by 25 m in the Measured Mineral Resource area, 50 m by 50 m in the Indicated area, and up to 200 m by 200 m in the Inferred areas. A drill hole collar plot is presented in Figure 1.

## Sampling and Sub-sampling Techniques

Samples are splits of the diamond core with average lengths of 1 m (PQ diameter core) or 2 m (NQ and HQ core). For the NQ and HQ core, predominantly half core splits were taken, with some quarter core sample splits also taken. PQ core was fully consumed by sampling within the mineralized zones, as determined by the supervising geologist.

The 2023 core samples were collected from the bastnaesite mineralisation with lengths ranging from 0.35 to 2.45 m, with typical sample length between 1.0 to 2.0 m. The sampling

lengths were dictated by the lithology of the core, with half core samples taken and dispatched for sample analysis. Samples in 2007 were submitted to ActLabs for sample analyses, 2008 samples were submitted to ACME, and all samples since 2009 were submitted to ALS Global. All laboratories used are ISO-certified and independent of Vital.

### Sample Analysis Methods

NQ and HQ drill core was crushed to 90% passing 10 mesh (2.0 mm). The PQ core was crushed to 6-mesh (approximately 3.3 mm) and approximately 2.0 kg was split off using a rotary splitter which was then crushed to 10-mesh. Splits of 250 g pulps were prepared from the 10-mesh crushed core.

For drill hole samples collected by previous owner Avalon, the REE concentrations were determined using inductively coupled plasma mass spectrometry (ICP-MS) and X-ray fluorescence (XRF) for the highest concentrations by several different geochemical laboratories. Analytical methods include lithium metaborate/tetraborate fusion (Actlabs), in some cases followed by dilute nitric digestion (ACME, ALS) of 0.1 g of pulp followed by multi-element ICP-MS analysis. Samples with high REE values were analyzed via XRF or further diluted using ICP-MS. The analyses of the REE are considered total analyses. Elemental assay results were reported and were converted to their oxides using appropriate stoichiometric conversions. The oxides for the rare earths (REO) were subsequently used for all Mineral Resource estimation studies and reporting.

Appropriate Quality Assurance and Quality Control (QAQC) measures were implemented for all stages of drilling since 2007, which support the MRE. Certified Reference Materials (CRM), blanks, and field and laboratory duplicates were used to monitor the accuracy and precision of sampling and sample analyses.

For the Avalon drilling (2007 – 2014), the pulp of every 10<sup>th</sup> sample was analyzed by a secondary laboratory. Every 40<sup>th</sup> sample was a blank and one of several in-house standards was inserted as every 15<sup>th</sup> sample. Assay batches that did not meet the quality control criteria were re-assayed. For the 2021 to 2023 drilling programs by Vital, blanks and external REE standards supplied by Avalon were inserted at the same ratio as the Avalon drilling programs. Results of the QAQC programs indicate acceptable levels of accuracy and precision of analytical results.

### Data Verification and Check Assay Program

The sampling techniques and assay data for the Avalon and Vital Metals drilling programs have been independently reviewed by the CPs for data verification purposes.

The CPs have also reviewed the sampling and QAQC protocols for the 2021-2023 drilling programs and noted no major issues. The CPs highly recommend as part of its revised QAQC and data verification program, Vital Metals complete routine audits of its primary certified and independent assay laboratory including sending a certain number of drill core samples to a secondary certified and independent assay laboratory for comparative testing purposes and to check for any laboratory biases or significant errors. The CPs also reviewed and validated the drill hole database used in the current MRE. Recommendations for updates to Vital Metals' core logging, sampling, and QAQC procedures to meet current mining industry best practices are noted in several sections above.

A total of eight (8) quarter core check assay samples from 2021 and 2023 drill holes were submitted by the CPs to Activation Laboratories Ltd. (ActLabs) for sample preparation and assay analysis using lithium metaborate/tetraborate fusion with subsequent analysis by ICP and ICP/MS. Actlabs is independent of Vital Metals. These check assay samples were collected by the CPs for data verification purposes and for comparing assay results between two independent assay laboratories (original ALS assay results versus ActLabs check assay results).

The presence of REE mineralisation was confirmed in the 8 check assay samples, and the CPs confirm that the ActLabs check assay results were similar to the original ALS assay results from the same sample intervals.

The CPs are of the opinion that sampling methods, sample preparation, security and analytical procedures implemented by Avalon and Vital Metals for the Tardiff deposit are acceptable for the purposes of reporting the current MRE.

### Estimation Methodology

A block model with parent cell sizes of 12.5 m (E) by 12.5 m (N) by 5 m (Z) was constructed, with block sizes approximately half the typical drill spacing, which generally supports a Measured or Indicated classification. Blocks and drill sample data were flagged according to the geological and mineralisation envelopes. Drill holes were composited to 2 m intervals, being the typical sample length, and composited sample data were statistically reviewed to determine appropriate top cuts for the REOs. The four mineralisation domains are treated as hard estimation domains, with variograms modelled for all light rare earth oxides (LREO) and selected heavy rare earth oxides and deleterious oxides, such as  $U_3O_8$ .

Ordinary kriging (OK) was used to interpolate all REO and  $Nb_2O_5$  grades using three estimation passes and variable sample ellipse orientation using Datamine's Dynamic Anisotropy function. A sample search ellipse with radii 100 m x 100 m x 10 m was used, with minimum 8 samples and maximum 22 samples per block estimate. A maximum of 4 samples per hole per block estimate was used. Top cut and composited sample assays were interpolated. LREO and HREO, and  $Nb_2O_5$  grades were also interpolated into the blocks located between the mineralisation domains. These domains are also hosted in syenite but not constrained by a mineralisation envelope, and were classified as Inferred. Diabase dykes and overburden were not interpolated with grade and assigned a value of 0 ppm for all interpolated oxides. A representative cross section showing block and drill hole grades is presented in Figure 2.

Density measurements were taken from drill core samples every 5 m on a 10 cm size core segment using the Archimedes method (water displacement). A total of 8,865 measurements have been taken since 2007, but no measurements were taken during the 2023 program. Density values were estimated into the block model using inverse distance squared using a single pass estimation. Blocks not estimated were assigned the domain mean density value, including 2.75 t/m<sup>3</sup> for the two main mineralisation zones.

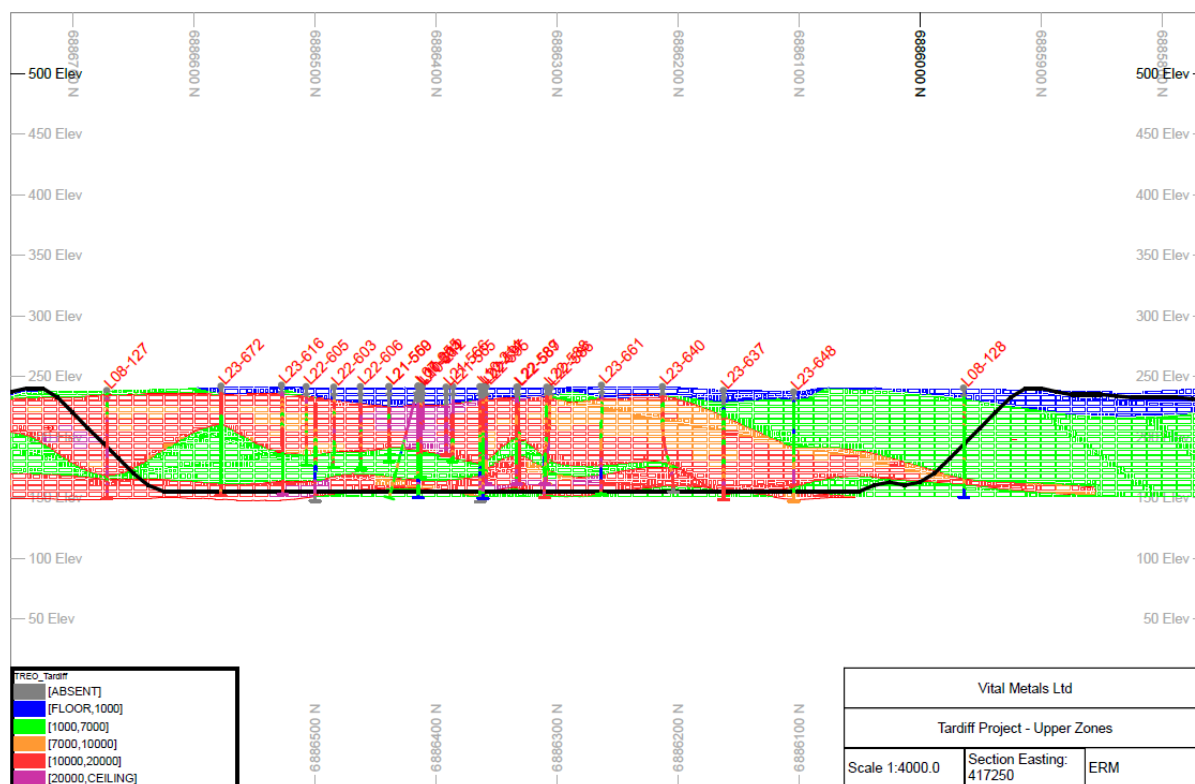

Figure 2: Cross section, Tardiff Mineral Resource, blocks and holes by TREO (PPM)

## Mineral Resource Classification

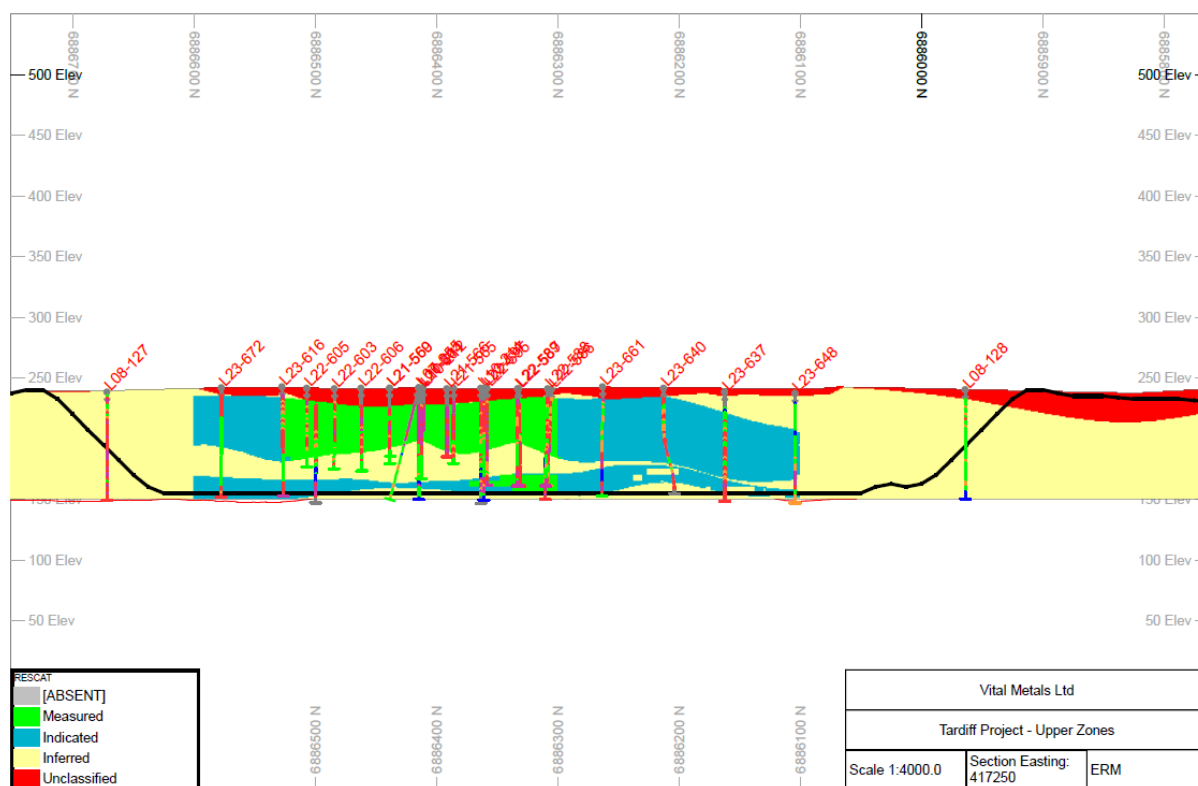

The MRE has been classified in accordance with the JORC Code (2012). The Competent Person classified the Tardiff Mineral Resource as Measured, Indicated, and Inferred based on drill hole spacing, the quality assurance of the data, geological confidence in the continuity of grade, quality of the local block grade estimates, and quantity and quality of density measurement data.

Measured Mineral Resources are located within volumes supported by drill spacing of approximately 25 m by 25 m; Indicated resources supported by drill spacing of approximately 50 m by 50 m; and Inferred out to 200 m drill spacing. Polygons were digitised for the two main mineralisation domains using the above guidelines. The polygons were used as 'cookie cutters' to stamp the desired classification level into the block model, on a domain by domain basis. This provided the Competent Person complete control as to the assignment of classification into the block model.

Block model validation indicates that the final block classification is a reasonable representation of the input drill hole data and the geological features at the Project.

A representative cross section showing resource classification is presented in Figure 3, and a plan view of the classification is presented in Figure 1.

**Figure 3:** Cross section, Tardiff Mineral Resource, Resource Classification

## Cut-Off Grades

The MRE is reported within an optimised open pit shell, as presented in Figure 1, with input cost and mining parameters based upon the CP's experience with working on technical studies for other hard rock open pit projects in Canada.

The MRE is reported above a cut-off grade of 0.7% TREO, which is a break-even cutoff grade calculated using appropriate REO market prices, and recoveries for the individual REOs.

Details supporting the cutoff grade calculation and pit optimization are provided in JORC Table 1, Section 3.

## Mining and Metallurgical Methods

The CP has assumed that any mining of the Tardiff deposit will be by conventional open-pit mining methods. A Scoping Study is currently in progress to validate this assumption.

Metallurgical testwork is currently in progress to support the Scoping Study. Metallurgical recoveries determined from earlier technical studies for the project are considered to be reasonable, with average recoveries of 61% the TREOs. The recovery for niobium is currently low at 15%. Niobium is hosted in the mineral Fergusonite and Ferrocolumbite, which also host REE mineralisation, whereas the REE mineralisation is hosted predominantly in bastnasite and synchysite. It is a reasonable assumption, for the RPEEE test, that future metallurgical testwork will be targeted to allow for improved recoveries of Nb, and Vital are recommended to test this. These recoveries were used to support the open pit optimisation studies, used for reporting of this MRE.

The pit optimization studies used revenues determined using market pricing for the rare earth oxides, as well as the 2024 metallurgical results from Corem laboratories in Quebec, Canada for mining recovery, dilution, and refining and payability assumptions. A typical working season of 8 months/annum at the extreme cold latitude as well as cost data for mining, processing, camp and contingency was also included in the revenue estimation. The train transport costs were identified as important to project cost understanding and were derived from CN rail advertised pricing, and barge transport costs across Slave Lake.

### Competent Person's Statements

The information in this report that relates to the current Mineral Resource estimate is based on, and fairly reflects, information compiled by Mr David Williams and Mr Paul Teniere. Mr. David Williams (B. Sc. Hons) is a full-time employee of ERM and is a Member of the Australian Institute of Geoscientists (RPGEO). Mr. Paul Teniere, M.Sc., P.Geo. is the Owner and President of Teniere Geoconsulting Services and a Member of the Association of Professional Engineers & Geoscientists of New Brunswick (APEGNB) and Professional Engineers and Geoscientists of Newfoundland & Labrador (PEGNL), both considered recognized overseas professional organizations (ROPO) under JORC. Mr David Williams and Mr Paul Teniere are fully independent of Vital Metals and have sufficient experience relevant to the style of mineralisation and type of deposit under consideration and to the activity which they are undertaking to qualify as Competent Persons as defined in the 2012 Edition of the Australasian Code for the Reporting of Exploration Results, Mineral Resources and Ore Reserves (JORC Code). Mr David Williams and Mr Paul Teniere consent to the disclosure of the information in this report in the form and context in which it appears. Mr Paul Teniere assumes responsibility for matters related to Sections 1 and 2 of JORC Table 1, while Mr David Williams assumes responsibility for matters related to Section 3 of JORC Table 1.

The information in this report that relates to Metallurgical Results is based on information compiled by Principal Technical Consultant, Richard Wagner, (Bachelor Applied Science, Mining Engineering, Mineral Processing), a Competent Person, who is a member of the Professional Engineers of Ontario, Canada (PEO) since 1982. Mr Wagner is a casual time employee of ERM. Mr Wagner has sufficient experience which is relevant to the style of mineralisation and type of deposit under consideration and to the activity which is undertaken, to qualify as a Competent Person as defined in the 2012 Edition of the 'Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves'. Mr Wagner consents to the inclusion in the presentation of the matters based on the information made available to him, in the form and context in which it appears.

## About Vital Metals

Vital Metals Limited (ASX: VML) is developing the large Nechalacho Rare Earth Project in Canada's Northwest Territories. Nechalacho has the potential to underpin a significant rare earths supply chain for North America with responsibly sourced critical minerals for the green economy transformation.

## Forward Looking Statements

This release includes forward looking statements. Often, but not always, forward looking statements can generally be identified by the use of forward-looking words such as "may", "will", "expect", "intend", "plan", "estimate", "anticipate", "continue", and "guidance", or other similar words and may include, without limitation statements regarding plans, strategies and objectives of management, anticipated production or construction commencement dates and expected costs or production output.

Forward looking statements inherently involve known and unknown risks, uncertainties and other factors that may cause the company's actual results, performance and achievements to differ materially from any future results, performance or achievements. Relevant factors may include, but are not limited to, changes in commodity prices, foreign exchange fluctuations and general economic conditions, increased costs and demand for production inputs, the speculative nature of exploration and project development, including the risks of obtaining necessary licences and permits and diminishing quantities or grades of resources or reserves, political and social risks, changes to the regulatory framework within which the company operates or may in the future operate, environmental conditions including extreme weather conditions, recruitment and retention of personnel, industrial relations issues and litigation.

Forward looking statements are based on the company and its management's good faith assumptions relating to the financial, market, regulatory and other relevant environments that will exist and affect the company's business and operations in the future. The company does not give any assurance that the assumptions on which forward looking statements are based will prove to be correct, or that the company's business or operations will not be affected in any material manner by these or other factors not foreseen or foreseeable by the company or management or beyond the company's control.

Although the company attempts to identify factors that would cause actual actions, events or results to differ materially from those disclosed in forward looking statements, there may be other factors that could cause actual results, performance, achievements or events not to be anticipated, estimated or intended, and many events are beyond the reasonable control of the company. Accordingly, readers are cautioned not to place undue reliance on forward looking statements.

Forward looking statements in this release are given as at the date of issue only. ## JORC Code, 2012 Edition – Table 1

### Section 1 Sampling Techniques and Data

| Criteria                   | JORC Code explanation   | Commentary   |
|----------------------------|---|--|
| <b>Sampling techniques</b> | <ul style="list-style-type: none"> <li><i>Nature and quality of sampling (eg cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling.</i></li> <li><i>Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.</i></li> <li><i>Aspects of the determination of mineralisation that are Material to the Public Report.</i></li> <li><i>In cases where ‘industry standard’ work has been done this would be relatively simple (eg ‘reverse circulation drilling was used to obtain 1 m samples from which 3 kg was pulverised to produce a 30 g charge for fire assay’). In other cases more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (eg submarine nodules) may warrant disclosure of detailed information.</i></li> </ul> | <ul style="list-style-type: none"> <li>Samples at the Tardiff Deposit Upper Zone (Tardiff or Tardiff deposit) are splits of diamond drill core over average lengths of one metre (PQ [85 mm] diameter core) or two metres (NQ [47.6 mm] and HQ [63.5 mm] diameter) or less in some cases. Of the NQ and HQ diameter core, a half or quarter mechanical split was sampled; the PQ diameter core was sampled entirely in the mineralized zones and a third of the core was sawn and sampled in unmineralized or weakly mineralized zones. The drill core was crushed and splits for geochemical analysis were prepared by independent laboratories.</li> <li>Drill core is marked with a centre line for the sampler to ensure no sampling bias was introduced by choosing the location of the split and ensuring the samples are representative.</li> <li>NQ and HQ drill core was crushed to 90% passing 10 mesh (2.0 mm). The PQ core was crushed to 6-mesh (approximately 3.3 mm) and approximately 2.0 kg was split off using a rotary splitter which was then crushed to 10-mesh. Splits of 250 g pulps were prepared from the 10-mesh crushed core.</li> <li>Sampling of 2023 diamond drill core completed by Vital Metals are half splits of HQ-diameter drill core using a core splitter. A limited number of holes were cut with a core saw.</li> <li>2023 core samples were collected from the bastnaesite mineralisation with lengths ranging from 0.35 to 2.45 m. The typical sample length was 1.0 to 2.0 m. The sampling lengths were dictated by the lithology of the core.</li> <li>All drill core samples were crushed to 90% &lt;2 mm, then 1 kg was riffle split. The 1 kg splits from the samples were then pulverized to 85% &lt;75 µm.</li> </ul> |
| <b>Drilling techniques</b> | <ul style="list-style-type: none"> <li><i>Drill type (eg core, reverse circulation, open-hole hammer, rotary air blast, auger, Bangka, sonic, etc) and details (eg core diameter, triple or standard tube, depth of diamond tails, face-sampling bit or other type, whether core is oriented and if so, by what method, etc).</i></li> </ul>  | <ul style="list-style-type: none"> <li>Diamond core drilling using PQ, NQ, and HQ diameter core tubes with wireline recovery was used for all the drilling at Tardiff. A limited number of oriented core holes were drilled by Avalon for geotechnical purposes.</li> <li>HQ diameter diamond drilling was used for the 2023 drill program by Vital Metals. As the holes were short and vertical no orientations of the 2023 drill cores were undertaken.</li> </ul>   |

| Criteria                       | JORC Code explanation  | Commentary  |
|--------------------------------|--|---|
| <b>Drill sample recovery</b>   | <ul style="list-style-type: none"> <li>Method of recording and assessing core and chip sample recoveries and results assessed.</li> <li>Measures taken to maximise sample recovery and ensure representative nature of the samples.</li> <li>Whether a relationship exists between sample recovery and grade and whether sample bias may have occurred due to preferential loss/gain of fine/coarse material.</li> </ul>                           | <ul style="list-style-type: none"> <li>Rock quality designation (RQD) logging was performed on all drill holes starting in 2009.</li> <li>The weathering profile at Tardiff is limited and core recovery was generally excellent. RQD averaged 96.2% with a median of 98.7%.</li> <li>The split lines were marked on the core to ensure systematic representative sampling.</li> <li>There is no relationship between core recovery and grade, and preferential loss or gain of material during sample capture is not expected or thought to bias sample results at the Project.</li> <li>Good core recovery was observed for the 2023 drill program.</li> <li>The geological nature of the mineralisation in the Upper Zone (is secondary alteration products associated with predominantly carbonates (i.e. bastnaesite, synchisite etc.) and phosphates (i.e. monazite) and lesser amount of silicates (i.e. allanite, fergusonite).</li> </ul>  |
| <b>Logging</b>                 | <ul style="list-style-type: none"> <li>Whether core and chip samples have been geologically and geotechnically logged to a level of detail to support appropriate Mineral Resource estimation, mining studies and metallurgical studies.</li> <li>Whether logging is qualitative or quantitative in nature. Core (or costean, channel, etc) photography.</li> <li>The total length and percentage of the relevant intersections logged.</li> </ul> | <ul style="list-style-type: none"> <li>Logging was completed by qualified personnel by Avalon (historically) and Vital Metals for the 2021 to 2023 drilling programs. Detailed lithology logs include a description of alteration, texture, mineralogy, and mineralisation.</li> <li>All drill core in the 2021 to 2023 drilling programs were photographed digitally and the database of these photos is maintained by Vital Metals. Select drill holes were re-photographed by Vital Metals using high resolution photography in summer 2024.</li> <li>Logging information from a total of 25,393 sample intersections from 613 drill holes within the Tardiff area with a total length of 55,834 m were used for constructing the wireframes for the mineralized domains. Qualitative lithological logs for 100% of the intersections were available.</li> <li>Total length of the core for the 74 holes of the 2023 drilling program is 6,664 m and the core was 100% logged.</li> <li>In the CPs opinion, the logging is adequate to support Mineral Resource estimation.</li> </ul> |
| <b>Sub-sampling techniques</b> | <ul style="list-style-type: none"> <li>If core, whether cut or sawn and whether quarter, half or all core taken.</li> <li>If non-core, whether riffled, tube sampled, rotary split, etc and whether sampled wet or dry.</li> </ul>   | <ul style="list-style-type: none"> <li>Of the NQ and HQ diameter core, a half or quarter mechanical split was sampled; the PQ diameter core was sampled entirely in the mineralized zones; and approximately 1/3 of the drill core was sawn and sampled in unmineralized or weakly mineralized zones.</li> </ul>  |

| Criteria  | JORC Code explanation  | Commentary   |
|---|--|--|
| <b>and sample preparation</b>                     | <ul style="list-style-type: none"> <li>For all sample types, the nature, quality and appropriateness of the sample preparation technique.</li> <li>Quality control procedures adopted for all sub-sampling stages to maximise representivity of samples.</li> <li>Measures taken to ensure that the sampling is representative of the in situ material collected, including for instance results for field duplicate/second-half sampling.</li> <li>Whether sample sizes are appropriate to the grain size of the material being sampled.</li> </ul>   | <ul style="list-style-type: none"> <li>Sampling procedures of mechanical or sawn splits of core follows industry standard practice and is considered by the CPs to be appropriate for hard rock deposits.</li> <li>Drill core sample lengths ranged from 0.2 m to 5.9 m with 2 m as the most common sample length, and nearly 90% ranged from 1.0 m to 3.0 m.</li> <li>The core samples were bagged and sealed at the Project site; crushing and pulverization were performed by the primary laboratory, ALS Canada.</li> <li>Duplicate analyses of the rejects and the pulps were routinely performed for the Avalon drilling.</li> <li>Avalon performed 87 field duplicate analyses of drill core, which indicated acceptable reproducibility.</li> <li>Half core splits were sampled from the 2023 Vital Metals drilling program. The sampled core was crushed before assaying to ensure the material from the entire interval was analysed during the assaying process.</li> <li>Duplicates of both the coarse-crushed (&lt;2 mm) rejects and of the assay pulps were analysed and showed good reproducibility of the REE assays, indicating that both materials are sufficiently homogeneous.</li> <li>The core sample intervals honour the interpreted contacts of the mineralisation zones, thus providing adequate sample coverage.</li> <li>The sample lengths are considered appropriate for the rock type and mineralisation style by the CPs.</li> </ul> |
| <b>Quality of assay data and laboratory tests</b> | <ul style="list-style-type: none"> <li>The nature, quality and appropriateness of the assaying and laboratory procedures used and whether the technique is considered partial or total.</li> <li>For geophysical tools, spectrometers, handheld XRF instruments, etc, the parameters used in determining the analysis including instrument make and model, reading times, calibrations factors applied and their derivation, etc.</li> <li>Nature of quality control procedures adopted (eg standards, blanks, duplicates, external laboratory checks) and whether acceptable levels of accuracy (ie lack of bias) and precision have been established.</li> </ul> | <ul style="list-style-type: none"> <li>The analyses of the REE are considered total analyses. The methods include lithium metaborate/tetraborate fusion (Actlabs), in some cases followed by dilute nitric digestion (ACME, ALS) of 0.1 g of pulp followed by multi-element ICP-MS analysis. Samples with high REE values were analyzed via XRF or further diluted using ICP-MS. These methods are considered appropriate for REE analysis.</li> <li>For drill hole samples collected by previous owner Avalon Advanced Materials Inc. (Avalon), the Rare Earth Element (REE) concentrations were determined using inductively coupled plasma mass spectrometry (ICP-MS) and X-ray fluorescence (XRF) for the highest concentrations by several different geochemical laboratories. The laboratory packages used were 4B2-STD and 4B2- RESEARCH (ACME Laboratories Ltd. [ACME]), 4B (Activation Laboratories Ltd. [Actlabs]), and ME-MS81d, ME-MS81h, and</li> </ul>   |

| Criteria | JORC Code explanation | Commentary  |
|----------|-----------------------|---|
|          |                       | <p>XRF10 (ALS Laboratories [ALS]). The majority of the samples completed by Vital Metals were analyzed by ALS.</p> <ul style="list-style-type: none"> <li>• All 2021, 2022, and 2023 Vital Metals core samples were submitted to ALS for sample preparation and assay analysis by lithium borate fusion with ICP-MS analysis (ME-MS81h).</li> <li>• Handheld XRF was only used as a guide for drill core logging.</li> <li>• The accuracy of the assaying has been validated through a combination of using certified reference standards with a known grade and inserting field blanks.</li> <li>• For the Avalon drilling, the pulp of every 10th sample was analyzed by a secondary laboratory. Every 40th sample was a blank and one of several in-house standards was inserted as every 15th sample. Assay batches that did not meet the quality control (QC) criteria were re-assayed. For the 2021 to 2023 drilling programs by Vital Metals, blanks and external REE standards supplied by Avalon were inserted at the same ratio as the previous drilling programs. Results of the QAQC program indicate acceptable levels of accuracy and precision of analytical results. However, the CP recommends using new certified reference materials (CRMs) for all future drilling programs.</li> <li>• A total of 8 independent witness (IW) quarter core check assay samples from 2021 and 2023 drill holes were submitted by the CPs and Vital Metals to Activation Laboratories (ActLabs) for sample preparation and assay analysis using lithium metaborate/tetraborate fusion with subsequent analysis by ICP and ICP/MS. Actlabs is independent of Vital Metals and ERM. These check assay samples were collected at the request of the CPs for data verification purposes and for comparing assay results between two independent laboratories (ALS versus ActLabs).</li> <li>• The presence of REE mineralisation (TREO) was confirmed in the 8 check assay samples, and the CPs confirm that the ActLabs check assay results were similar to the original ALS assay results from the same intervals.</li> <li>• Field blanks were inserted to monitor contamination and results were acceptable.</li> <li>• It is the opinion of CPs that sampling methods, sample preparation, security and analytical procedures implemented by Avalon and Vital Metals for the Tardiff Deposit are acceptable for the purposes of reporting a Mineral</li> </ul> |

| Criteria                                     | JORC Code explanation   | Commentary   |
|--|---|--|
|  |   | <p>Resource Estimate.</p> <ul style="list-style-type: none"> <li>Several items were noted during the CPs QAQC drill hole database review and data verification exercise that necessitates changes to Vital Metals' core logging, sampling, and QAQC program in order to meet current industry best practices for Mineral Exploration. This includes the use of CRMs from accredited CRM providers; the use of a relational logging and assay database for core logging to ensure data integrity and quality controls; and consistent entry of hole information, geotechnical and core recovery data, and CRM laboratory results. The sampling and QAQC procedures adopted to support this Mineral Resource have not negatively influenced the classification of the Mineral Resource. Vital Metals has already taken steps to update their core logging, sampling, and QAQC procedures for all future drilling programs to ensure they meet current mining industry best practice guidelines.</li> </ul> |
| <b>Verification of sampling and assaying</b> | <ul style="list-style-type: none"> <li><i>The verification of significant intersections by either independent or alternative company personnel.</i></li> <li><i>The use of twinned holes.</i></li> <li><i>Documentation of primary data, data entry procedures, data verification, data storage (physical and electronic) protocols.</i></li> <li><i>Discuss any adjustment to assay data.</i></li> </ul> | <ul style="list-style-type: none"> <li>No twinned holes were drilled. However, in multiple cases, zones of REE mineralisation were intersected from different drill hole collar locations. The 2023 drilling program by Vital Metals further infilled the existing Indicated Mineral Resource or helped increase the confidence in resource categories and determining grade continuity in the Tardiff deposit.</li> <li>Rare Earth Oxide (REO) values were calculated from the ppm assay values from the REE assay results. The following conversion factors were used: <ul style="list-style-type: none"> <li>Ce CeO2 1.228</li> <li>Dy Dy2O3 1.148</li> <li>Er Er2O3 1.143</li> <li>Eu Eu2O3 1.158</li> <li>Gd Gd2O3 1.153</li> <li>Ho Ho2O3 1.146</li> <li>La La2O3 1.173</li> <li>Lu Lu2O3 1.137</li> <li>Nd Nd2O3 1.166</li> <li>Pr Pr6O11 1.207</li> <li>Sm Sm2O3 1.16</li> <li>Tb Tb4O7 1.175</li> </ul> </li> </ul>   |

| Criteria                       | JORC Code explanation  | Commentary  |
|--------------------------------|--|---|
|                                |  | <ul style="list-style-type: none"> <li>○ Tm Tm<sub>2</sub>O<sub>3</sub> 1.142</li> <li>○ Y Y<sub>2</sub>O<sub>3</sub> 1.27</li> <li>○ Yb Yb<sub>2</sub>O<sub>3</sub> 1.139</li> </ul> <ul style="list-style-type: none"> <li>• Drill hole data were maintained in a Maxwell Datashed database by Avalon and in a Microsoft Access Database by Vital Metals. ERM recompiled the Vital Metals assay data from the original laboratory certificates prior to merging with the Avalon portion of the database.</li> <li>• It is the opinion of the CPs that mining industry standard procedures were followed for data entry, data verification, and digital data storage.</li> </ul>   |
| <b>Location of data points</b> | <ul style="list-style-type: none"> <li>• <i>Accuracy and quality of surveys used to locate drill holes (collar and down-hole surveys), trenches, mine workings and other locations used in Mineral Resource estimation.</i></li> <li>• <i>Specification of the grid system used.</i></li> <li>• <i>Quality and adequacy of topographic control.</i></li> </ul> | <ul style="list-style-type: none"> <li>• All drill hole collar locations are initially surveyed using a handheld GPS and final collar coordinates were then confirmed by registered surveyors using high-precision DGPS surveying equipment.</li> <li>• All collar location data are in the UTM NAD83 Zone 12N coordinate system.</li> <li>• Down hole deviation surveys were completed on all drill holes used for Mineral Resource estimation.</li> <li>• A 0.5 m resolution satellite digital elevation survey was obtained by Avalon in 2010, which was previously used for mineral resource estimation purposes. A review of this DTM compared to the recent drill collars demonstrates some elevation differences between the DTM and selected drill hole collars, implying localised survey errors in the DTM.</li> <li>• Time limitations prevented Vital Metals acquiring a reliable topographic model to support this Mineral Resource estimate. Consequently, ERM constructed a topographic DTM using the drill hole collars.</li> <li>• The topographic DTM provides reliable coverage across the breadth of the deposit but at a localised scale, in areas in between drill holes, there will be minor differences between actual and modelled elevation.</li> <li>• A wireframe surface was constructed for the interpreted bathymetric surface of the lakes present at the project. Several small and shallow lakes are located on top of the Mineral Resource. The interpreted bathymetric model was used with the topographic DTM to appropriately deplete the resource block model.</li> <li>• The CPs regard the topographic DTM as used to support the Mineral resource as adequate quality.</li> </ul> |

| Criteria   | JORC Code explanation  | Commentary  |
|--|--|---|
| <b>Data spacing and distribution</b>                           | <ul style="list-style-type: none"> <li><i>Data spacing for reporting of Exploration Results.</i></li> <li><i>Whether the data spacing and distribution is sufficient to establish the degree of geological and grade continuity appropriate for the Mineral Resource and Ore Reserve estimation procedure(s) and classifications applied.</i></li> <li><i>Whether sample compositing has been applied.</i></li> </ul>                          | <ul style="list-style-type: none"> <li>The drill hole collars are spaced 25 m, 50 m, or wider in the less explored areas.</li> <li>In combination with geological and grade continuity in the deposit, in the CPs opinion, these spacings are considered adequate to support the Mineral Resource classifications applied.</li> <li>Grade estimation is based on drill hole assays composited to two metre intervals within the intercepts of the mineralized zones. Residuals were distributed equally through the intercept.</li> </ul>   |
| <b>Orientation of data in relation to geological structure</b> | <ul style="list-style-type: none"> <li><i>Whether the orientation of sampling achieves unbiased sampling of possible structures and the extent to which this is known, considering the deposit type.</i></li> <li><i>If the relationship between the drilling orientation and the orientation of key mineralised structures is considered to have introduced a sampling bias, this should be assessed and reported if material.</i></li> </ul> | <ul style="list-style-type: none"> <li>The zones of REE mineralisation are sub-horizontal magmatic layers which have not been structurally modified. Drill hole dip ranges from -45° to -90°, averaging -76°. All 2023 drill holes were drilled at -90° to intersect horizontally layered REO mineralisation at 90° to achieve unbiased sampling.</li> <li>The mineralisation was intersected at appropriate angles for the deposit type.</li> <li>The apparent mineralisation intersections may be longer than true thicknesses in cases where the drill hole is not vertical.</li> </ul>                            |
| <b>Sample security</b>   | <ul style="list-style-type: none"> <li><i>The measures taken to ensure sample security.</i></li> </ul>   | <ul style="list-style-type: none"> <li>All assay samples were sealed using zip lock bags and multiple samples were then placed in rice bags sealed with zip locks. The independent laboratory verified sealed sample integrity upon receipt.</li> <li>Analyses for elements such as REE's, niobium, and zircon are unlikely to be altered as a result of insecurity of samples such as contamination.</li> <li>Samples were collected and sent to an independent laboratory (ALS) using mining industry standard chain of custody procedures and the CP has verified these procedures and has no concerns.</li> </ul> |
| <b>Audits or reviews</b>                                       | <ul style="list-style-type: none"> <li><i>The results of any audits or reviews of sampling techniques and data.</i></li> </ul>   | <ul style="list-style-type: none"> <li>The sampling techniques and data for the Avalon and Vital Metals drilling programs have been independently reviewed by the CPs for data verification purposes.</li> <li>The CPs have reviewed the sampling and QAQC protocols for the 2021-2023 drilling programs and noted no major issues. The CPs highly recommend as part of its revised QAQC and data verification program, Vital Metals complete routine audits of its primary certified and independent assay laboratory including sending a certain number of drill core samples to a</li> </ul>                       |

| Criteria | JORC Code explanation | Commentary  |
|----------|-----------------------|---|
|          |                       | secondary certified and independent assay laboratory for comparative testing purposes and to check for any laboratory biases or significant errors. The CPs also reviewed and validated the drill hole database used in the current mineral resource estimate. Recommendations for updates to Vital Metals' core logging, sampling, and QAQC procedures to meet current mining industry best practices are noted in several sections above. |

## Section 2 Reporting of Exploration Results

|                                  |   | <p>and photography facilities in the Tardiff field camp, and also completed a drill hole GPS collar check south of Thor Lake from the 2022 and 2023 Vital Metals drilling programs. The handheld GPS collar checks matched the original surveyed coordinates. After the site visit, CP Paul Teniere supervised the collection of 8 independent witness (IW) quarter core check samples from 2021 and 2023 Vital Metals drilling programs for laboratory testing, and to verify that REE mineralization exists and closely matches the original assay results from the same sampled intervals.</p> <ul style="list-style-type: none"> <li>ERM Principal Mining Engineer, James Gardner was accompanied by Vital Metals mining consultant Eric Vinet (P.Eng.) on the site visit and using a helicopter travelled to different points taking georeferenced (northing, easting) based photos with notes about as-built structures, locations of proposed mining infrastructure as part of the scoping study. Major as-built areas include Thor Lake Camp which is a 40-person exploration camp, and North T site which is a previously mined pit and has a water retention pond, waste rock dumps, a Tomra ore sorter and conveyor and mining equipment. There were no observed discrepancies from the report on buildings or equipment listed in engineering notes. Major infrastructure proposed and discussed between Vital Metals and ERM include a barge conveyor loading site, a run of mine area, haulage roads, a secondary mine camp. The logistics of transport were discussed, a project barge loading location on the north shore of Great Slave Lake, connects the project by water to Hay River Marine Terminal and freight yard on the south Shore. From Hay River the CN railway connects to Canada and USA via multiple railways and by roads etc. to the greater North American refineries including United States, Canada, Greenland, Mexico and Central America.</li> </ul> |
| <b>Geological interpretation</b> | <ul style="list-style-type: none"> <li>Confidence in (or conversely, the uncertainty of ) the geological interpretation of the mineral deposit.</li> <li>Nature of the data used and of any assumptions made.</li> <li>The effect, if any, of alternative interpretations on Mineral Resource estimation.</li> <li>The use of geology in guiding and controlling Mineral Resource estimation.</li> <li>The factors affecting continuity both of grade and geology.</li> </ul> | <ul style="list-style-type: none"> <li>The Tardiff deposit is hosted by the Nechalacho Nepheline Syenite and consists of a layered series of rocks with increasing peralkaline characteristics at depth. It is virtually undeformed, and the rock units and mineralisation are generally sub-horizontal and can be traced for hundreds of metres.</li> <li>The REE mineralisation is hosted in mafic, hydrothermally altered eudialyte-aegirine-nepheline syenite. The Nechalacho deposit alteration system (biotite- magnetite-chlorite-quartz-zircon) varies between 80 m (L08-65) and 190 m (L08- 127) in vertical thickness, with the alteration typically starting at the surface. The alteration zone coincides with REE, Zr, Nb, and Ta mineralisation, with average values over the whole mineralized package of</li> </ul>   |

| Criteria | JORC Code explanation | Commentary  |
|----------|-----------------------|---|
|          |                       | <p>approximately 0.75% to 1.0% Total Rare Earth Oxides (TREO).</p> <ul style="list-style-type: none"> <li>• There are some trends in chemical and mineralogical characteristics in the Nechalacho deposit that have both geological and metallurgical significance. These trends are most apparent in vertical zoning of the deposit with respect to the proportion of heavy rare earth elements (HREE) and light rare earth elements (LREE). In general, the HREE relative to the LREE show a distinct vertical zonation with increasing HREE to depth. This is not always consistent in individual drill holes.</li> <li>• Geological continuity and mineralisation are supported by close-spaced drilling and variography. The layered mineralisation is reasonably predictable and observable in the drill holes.</li> <li>• The nepheline syenite intrusion contacts are sharp and provide an outer limit to the mineralisation.</li> <li>• The continuity of the mineralisation is largely controlled by the deposition of eudialyte crystals in magmatic cumulate layers and by the interstitial crystallization of eudialyte in distinct horizons. The mineralized magmatic layers typically display sharp lower undulating boundaries and more gradual upper boundaries.</li> <li>• Localized hydrothermal REE-mobilization and redeposition in small, locally semi-massive bastnäsite veins and pervasive disseminated zones is less predictable. Constraining these zones within wireframes is not possible at the current drill spacing.</li> <li>• A nominal 7,000 ppm (0.7%) TREO value combined with lithological logging information was used for developing mineralogical wireframes in Leapfrog Geo software (mineralisation models 1, 2, 3, and 4). The cut-off grade was previously used to support the previous Mineral Resource (published 4<sup>th</sup> April 2024) and is supported by analysis of a log-probability plot of sample assays for TREO. Approximately 50% of the TREO assays have grades &gt; 7,000 ppm TREO.</li> <li>• The mineralized domains (or resource domains) were modelled as sub-horizontal magmatic layers, and the footwall surface of the mineralized domains is controlled by collapsed fragments of the contact unit in several locations.</li> <li>• The Leapfrog model used to create the models supporting the previous Mineral Resource were updated using drill hole sample analyses from the</li> </ul> |

|          |                       | <p>test, that future metallurgical testwork will allow for improved recoveries of Nb, and Vital are recommended to test this.</p> <ul style="list-style-type: none"> <li>The reported Mineral Resource extends below shallow lakes to the north and south named Thor Lake and Long Lake. The North and South Tardiff small lakes reported with RPEEE Mineral Resource are also very shallow of less than 2 metre bathometric depth and do not host fish. It is expected that Vital Metals will remove these lakes on the property and obtain a permit with NWT Department of Fisheries, if required.</li> <li>Discussions were held between Vital Metals and the CPs regarding the RPEEE test, regarding the possibility to remove the lakes, and if environmental permitting is possible, or if it is not amenable due to Indigenous community stakeholders and the NWT government. The resulting dialogue with Vital Metals is as follows: <ul style="list-style-type: none"> <li>Indigenous stakeholders are willing to discuss and develop solutions to development of the resource under the Thor and Long lakes. A primary focus is that "Nechalacho's" or "Safe Harbour" in local language should be a site for a safe harbour for winter travel on the Great Slave Lake. Resource development concerns have largely centred around long term water contamination which Vital intends to work on with rigor, a desire to have renewal of mine projects in NWT and a desire to provide local services to project or work collaboratively/joint venture.</li> <li>Environmental permitting is considered to be a long-term task which also requires budget and technical study but is considered eventually possible to achieve. Vital has not yet attained the next stage of permitting beyond 2025. The application and related engagement process is underway and Vital are waiting on feedback.</li> <li>It's possible the operational plans will support a pumping capital project, if it has community approval and is permitted. However, no such operating plan has yet been decided or technical study commenced or engineered.</li> </ul> </li> </ul> |
